Documents of the World Radiocommunication Conference (WRC-2000) (Istanbul, 2000)

To reduce download time, the ITU Library and Archives Service has divided the conference documents into sections.

- This PDF includes Document No. 1-100
- The complete set of conference documents includes Document No. 1-544, DT No. 1-132 and DL No. 1-79.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

Document 1-E
20 January 2000
Original: English

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

Note by the Secretary-General

AGENDA OF THE CONFERENCE

The agenda of the World Radiocommunication Conference (WRC-2000) is contained in Resolution 1130 adopted by the Council.

The text of the resolution is attached.

Yoshio UTSUMI
Secretary-General

Annex: 1

ANNEX

RESOLUTION 1130

(approved at the twelfth Plenary Meeting)

AGENDA FOR THE WORLD RADIOCOMMUNICATION CONFERENCE (WRC-2000)

The Council,

noting

that Resolution 721 of the World Radiocommunication Conference (Geneva, 1997):

a) resolved to recommend to the Council that a world radiocommunication conference be held in Geneva in late 1999 for a period of four weeks;

b) recommended its agenda, and invited the Council to finalize the agenda and arrange for the convening of WRC-99 and to initiate as soon as possible the necessary consultation with Member States,

resolves

to convene a World Radiocommunication Conference (WRC-2000) in Istanbul (Turkey) from 8 May - 2 June 2000, with the following agenda:

1 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, taking account of the results of the 1997 World Radiocommunication Conference (WRC-97), and with due regard to the requirements of existing and future services in the bands under consideration, to consider and take appropriate action in respect of the following topics:

1.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, in accordance with Resolution **26 (Rev.WRC-97)**;

1.2 to finalize remaining issues in the review of Appendix **S3** to the Radio Regulations with respect to spurious emissions for space services, taking into account Recommendation **66 (Rev.WRC-97)** and the decisions of WRC-97 on adoption of new values, due to take effect at a future time, of spurious emissions for space services;

1.3 to consider the results of ITU-R studies in respect of Appendix **S7/28** on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services, and take the appropriate decisions to revise this Appendix;

1.4 to consider issues concerning allocations and regulatory aspects related to Resolutions **126 (WRC-97)**, **128 (WRC-97)**, **129 (WRC-97)**, **133 (WRC-97)**, **134 (WRC-97)** and **726 (WRC-97)**;

1.5 to consider regulatory provisions and possible additional frequency allocations for services using high altitude platform stations, taking into account the results of ITU-R studies conducted in response to Resolution **122 (WRC-97)**;

1.6 issues related to IMT-2000;

1.6.1 review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary;

1.6.2 identification of a global radio control channel to facilitate multimode terminal operation and worldwide roaming of IMT-2000;

1.7 review of the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to protecting operational, distress and safety communications, taking into account Resolution **346 (WRC-97)**;

1.8 to consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service (FSS) networks in the bands 3 700 - 4 200 MHz and 5 925 - 6 425 MHz, including their coordination with other services allocated in these bands;

1.9 to take into account the results of ITU-R studies in evaluating the feasibility of an allocation in the space-to-Earth direction to the mobile-satellite service (MSS) in a portion of the 1 559 - 1 567 MHz frequency range, in response to Resolutions **213 (Rev.WRC-95)** and **220 (WRC-97)**;

1.10 to consider results of ITU-R studies carried out in accordance with Resolution **218 (WRC-97)** and take appropriate action on this subject;

1.11 to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions **214 (Rev.WRC-97)** and **219 (WRC-97)**;

1.12 to consider the progress of studies on sharing between feeder links of non-GSO MSS networks and GSO FSS networks in the bands 19.3 - 19.7 GHz and 29.1 - 29.5 GHz, taking into account Resolution **121 (Rev.WRC-97)**;

1.13 on the basis of the results of the studies in accordance with Resolutions **130 (WRC-97)**, **131 (WRC-97)** and **538 (WRC-97)**:

1.13.1 to review and, if appropriate, revise the power limits appearing in Articles **S21** and **S22** in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services;

1.13.2 to consider the inclusion in other frequency bands of similar limits in Articles **S21** and **S22**, or other regulatory approaches to be applied in relation to sharing situations;

1.14 to review the results of the studies on the feasibility of implementing non-GSO MSS feeder links in the 15.43 - 15.63 GHz in accordance with Resolution **123 (WRC-97)**;

1.15 issues related to the radionavigation-satellite service:

1.15.1 to consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments;

1.15.2 to consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the bands 1 215 - 1 260 MHz and 1 559 - 1 610 MHz;

1.15.3 to consider the status of allocations to services other than the radionavigation-satellite service (Nos. **S5.355** and **S5.359**) in the band 1 559 - 1 610 MHz;

1.16 to consider allocation of frequency bands above 71 GHz to the earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution **723 (WRC-97)**;

1.17 to consider possible worldwide allocation for the earth exploration-satellite (passive) and space research (passive) services in the band 18.6 - 18.8 GHz, taking into account the results of the ITU-R studies;

1.18 to consider the use of new digital technology for the maritime mobile service in the band 156 - 174 MHz and consequential revision of Appendix **18/S18**, taking into account Resolution **342 (WRC-97)**;

1.19 to consider the report of the inter-conference representative group (IRG) submitted by the Director of the Radiocommunication Bureau and determine the basis for replanning by the next conference so as to afford each country an amount of spectrum that permits the economical development of a broadcasting-satellite service system;

1.19*bis* in accordance with Article S14, to consider objections expressed by administrations with respect to the Radio Regulations Board's Rules of Procedure relating to the application of RR 2674/S23.13 in order for the Bureau to modify its findings in accordance with the conclusions of the Conference;

1.20 to consider the issues related to the application of Nos. **S9.8**, **S9.9** and **S9.17** and the corresponding parts of Appendix **S5** with respect to Appendices **S30** and **S30A**, with a view to possible deletion of Articles 6 and 7 of Appendices **S30** and **S30A**, also taking into consideration Recommendation **35 (WRC-95)**;

1.21 to consider the report from the Radiocommunication Bureau on results of the analysis in accordance with Resolution **53 (WRC-97)** and take appropriate actions;

2 to examine the revised ITU-R recommendations incorporated by reference in the Radio Regulations in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;

3 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;

4 in accordance with Resolution **95 (WRC-97)**, to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

5 to review, and take appropriate action on, the report from the Radiocommunication Assembly submitted in accordance with Nos. 135 and 136 of the Convention (Geneva, 1992);

6 to identify those items requiring urgent action by the radiocommunication study groups in preparation for the next world radiocommunication conference;

7 in accordance with Article 7 of the Convention (Geneva, 1992):

7.1 to consider and approve the report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-97;

7.2 to recommend to the Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent Conference and on possible agenda items for future conferences,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a report to WRC-2000,

instructs the Secretary-General

1 to make all the necessary arrangements, in agreement with the Director of the Radiocommunication Bureau, for the convening and holding of the Conference;

2 to communicate this Resolution to concerned international and regional organizations.

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

Note by the Secretary-General

CREDENTIALS OF DELEGATIONS TO CONFERENCES

The provisions of the Convention of the International Telecommunication Union relating to credentials, as amended by the Plenipotentiary Conference (Minneapolis, 1998), are contained in Article 31, the text of which is attached.

Particular attention should be given to the following numbers:

		Nos.
–	the office of the signatory of the instruments of accreditation:	326
–	the wording of the instruments of accreditation, criteria to be employed:	328 to 331
–	credentials sent by telegram shall not be accepted:	338
–	the depositing of instruments of accreditation:	334

Yoshio UTSUMI
Secretary-General

Annex: 1

ANNEX

ARTICLE 31

Credentials for Conferences

324 **PP-98** 1 The delegation sent by a Member State to a plenipotentiary conference, a radiocommunication conference or a world conference on international telecommunications shall be duly accredited in accordance with Nos. 325 to 331 below.

325 2 1) Accreditation of delegations to Plenipotentiary Conferences shall be by means of instruments signed by the Head of State, by the Head of Government or by the Minister for Foreign Affairs.

326 2) Accreditation of delegations to the other conferences referred to in No. 324 above shall be by means of instruments signed by the Head of State, by the Head of Government, by the Minister for Foreign Affairs or by the Minister responsible for questions dealt with during the conference.

327 **PP-98** 3) Subject to confirmation prior to the signature of the Final Acts, by one of the authorities mentioned in Nos. 325 or 326 above, a delegation may be provisionally accredited by the head of the diplomatic mission of the Member State concerned to the host government. In the case of a conference held in the Swiss Confederation, a delegation may also be provisionally accredited by the head of the permanent delegation of the Member State concerned to the United Nations Office at Geneva.

328 3 Credentials shall be accepted if they are signed by one of the competent authorities mentioned in Nos. 325 to 327 above, and fulfil one of the following criteria:

329 – they confer full powers on the delegation;

330 – they authorize the delegation to represent its government, without restrictions;

331 – they give the delegation, or certain members thereof, the right to sign the Final Acts.

332 **PP-98** 4 1) A delegation whose credentials are found to be in order by the Plenary Meeting shall be entitled to exercise the right to vote of the Member State concerned, subject to the provisions of Nos. 169 and 210 of the Constitution, and to sign the final acts.

333 2) A delegation whose credentials are found not to be in order by the Plenary Meeting shall not be entitled to exercise the right to vote or to sign the Final Acts until the situation has been rectified.

334 **PP-98** 5 Credentials shall be deposited with the secretariat of the conference as early as possible. The committee referred to in No. 23 of Rules of Procedure of conferences and other meetings* be entrusted with the verification thereof and shall report on its conclusions to the Plenary Meeting within the time specified by the latter. Pending the decision of the Plenary Meeting thereon, any delegation shall be entitled to participate in the conference and to exercise the right to vote of the Member State concerned.

335 **PP-98** 6 As a general rule, Member States should endeavour to send their own delegations to conferences of the Union. However, if a Member State is unable, for exceptional reasons, to send its own delegation, it may give the delegation of another Member State powers to vote and sign on its behalf. Such powers must be conveyed by means of an instrument signed by one of the authorities mentioned in Nos. 325 or 326 above.

336 7 A delegation with the right to vote may give to another delegation with the right to vote a mandate to exercise its vote at one or more meetings at which it is unable to be present. In such a case it shall, in good time, notify the Chairman of the conference in writing.

337 8 A delegation may not exercise more than one proxy vote.

338 9 Credentials and transfers of powers sent by telegram shall not be accepted. Nevertheless, replies sent by telegram to requests by the Chairman or the secretariat of the conference for clarification of credentials shall be accepted.

339 **PP-98** 10 A Member State or an authorized entity or organization intending to send a delegation or representatives to a telecommunication standardization assembly, a telecommunication development conference or a radiocommunication assembly shall so inform the Director of the Bureau of the Sector concerned, indicating the names and functions of the members of the delegation or of the representatives.

---

* Note by the General Secretariat - The word "shall" should be inserted between the words "meetings" and "be".

PLENARY MEETING

Note by the Secretary-General

THE CPM REPORT TO THE 2000 WORLD RADIOCOMMUNICATION CONFERENCE

At the request of the Director of BR, I have the honour to submit to the Conference the Report of the CPM, prepared in response to ITU Council Resolution 1130 and as approved by the CPM Plenary Meeting on 26 November 1999.

Yoshio UTSUMI
Secretary-General

Annex: CPM Report to WRC-2000

ANNEX
(to WRC-2000, Document 3)

CPM Report on technical, operational and regulatory/procedural matters to be considered by the 2000 World Radiocommunication Conference

GENEVA, 1999

PREFACE

This CPM Report to the 2000 World Radiocommunication Conference (WRC-2000) was prepared in response to Resolution 1130 of the ITU Council to assist those who will be involved in the preparations for and deliberations at the WRC-2000. The Report was prepared and approved by the CPM at its second meeting, 15 - 26 November 1999. The Report is structured to generally follow the topics of the WRC-2000 Agenda and its contents follow the outline approved by the first meeting of the CPM which was held during the week following the WRC-97. A cross-reference list is provided to facilitate finding specific topics within the framework of the WRC-2000 Agenda. This Report comprises eight Chapters and one Annex.

The Report represents the best information on technical, operational and regulatory/procedural issues relevant to the WRC-2000 agenda available at the time of its preparation and should provide a good basis for the discussions at the Conference.

Robert W. Jones
Director Radiocommunication Bureau

Cross-reference between the WRC-2000 agenda items and the chapters of the CPM Report

WRC-2000 agenda item		Section of the CPM Report to WRC-2000
1	On the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, taking account of the results of WRC-97, and with due regard to the requirements of existing and planned services in the bands under consideration, to consider and take appropriate action in respect of the following topics:	
1.1	requests from administrations to delete their country footnotes or to have their country's name deleted from footnotes, if no longer required, in accordance with Resolution **26 (Rev.WRC-97)**;	Not in scope of CPM
1.2	to finalize remaining issues in the review of Appendix **S3** to the Radio Regulations with respect to spurious emissions for space services, taking into account Recommendation **66 (Rev.WRC-97)** and the decisions of WRC-97 on adoption of new values of spurious emissions for space services taking effect at a future time;	Chapter 7, § 7.1
1.3	to consider the results of ITU-R studies in respect of Appendix **S7 [28]** on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services and take the appropriate decisions to revise this Appendix;	Chapter 7, § 7.2
1.4	to consider issues concerning allocations and regulatory aspects related to Resolution **126 (WRC-97)** (the title may be found in § 7.4), Resolution **128 (WRC-97)** (the title may be found in § 7.4), Resolution **129 (WRC-97)** (the title may be found in § 7.4), Resolution **133 (WRC-97)** (the title may be found in § 7.4), Resolution **134 (WRC-97)** (the title may be found in § 7.4), Resolution **726 (WRC-97)** (the title may be found in § 7.4);	Chapter 6, § 6.1 § 6.1.1 § 6.1.4 § 6.1.5 § 6.1.2 § 6.1.5 § 6.1.3
1.5	to consider regulatory provisions and possible additional frequency allocations for services using high altitude platform stations, taking into account the results of ITU-R studies conducted in response to Resolution **122 (WRC-97)**;	Chapter 6, § 6.2
1.6	issues related to the IMT-2000;	Chapter 1
1.6.1	review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications, and priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary;	Chapter 1, § 1.1.1
1.6.2	identification of a global radio control channel to facilitate multimode terminal operation and worldwide roaming of IMT-2000;	Chapter 1, § 1.1.2
1.7	review of the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to protecting operational, distress and safety communications, taking into account Resolution **346 (WRC-97)**;	Chapter 1, § 1.2
1.8	to consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz, including their coordination with other services allocated in these bands;	Chapter 6, § 6.3
1.9	take into account the results of ITU-R studies in evaluating the feasibility of an allocation in the space-to-Earth direction to the mobile-satellite service in a portion of the 1 559-1 567 MHz frequency range, in response to Resolutions **213 (WRC-97)** and **220 (WRC-97)**;	Chapter 2, § 2.2

1.10	to consider results of ITU-R studies in accordance with Resolution **218 (WRC-97)** and take appropriate action on this subject;	Chapter 2, § 2.1
1.11	to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-GSO/MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions **214 (Rev.WRC-97)** and **219 (WRC-97)**;	Chapter 2, § 2.3
1.12	to consider the progress of studies on sharing between feeder links of non-geostationary-satellite networks in the mobile-satellite service and geostationary-satellite networks in the fixed-satellite service in the bands 19.3-19.7 GHz and 29.1-29.5 GHz taking into account Resolution **121 (Rev.WRC-97)**;	Chapter 6, § 6.4
1.13	on the basis of the results of the studies in accordance with Resolutions **130 (WRC-97)**, **538 (WRC-97)** and **131 (WRC-97)**:	Chapter 3
1.13.1	review and if appropriate, revise the power limits appearing in Articles **S21** and **S22** in relation to the sharing conditions among NGSO FSS, GSO FSS, GSO BSS, space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services;	Chapter 3
1.13.2	consider the inclusion in other frequency bands of similar limits in Articles **S21** and **S22**, or other regulatory approaches to be applied in relation to sharing situations;	Chapter 3
1.14	review the results of the studies on the feasibility of implementing non-GSO MSS feeder links in the 15.43-15.63 GHz in accordance with Resolution **123 (WRC-97)**;	Chapter 6, § 6.5
1.15	issues related to the radionavigation-satellite service:	Chapter 2, § 2.4
1.15.1	to consider new allocations to the radionavigation-satellite service required to support developments in the range from 1 to 6 GHz;	Chapter 2, § 2.4.1
1.15.2	to consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the 1 215-1 260 MHz and 1 559-1 610 MHz frequency bands;	Chapter 2, § 2.4.2
1.15.3	to consider the status of allocations to services other than the radionavigation-satellite (Nos. **S5.355** and **S5.359**) in the 1 559-1 610 MHz band;	Chapter 2, § 2.4.3
1.16	to consider allocation of frequency bands above 71 GHz to the earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution **723 (WRC-97)**;	Chapter 4, § 4.1
1.17	to consider possible worldwide allocation for the earth exploration-satellite (passive) and space research (passive) services in the band 18.6-18.8 GHz taking into account the results of the ITU-R studies;	Chapter 4, § 4.2
1.18	consider the use of new digital technology for the maritime-mobile service in the band 156-174 MHz and consequential revision of Appendix **S18 [18]** taking into account Resolution **342 (WRC-97)**;	Chapter 1, § 1.3
1.19	to consider the report of the IRG submitted by the Director of the BR and determine the basis for replanning by the next conference so as to afford each country an amount of spectrum that permits the economical development of a broadcasting-satellite service system;	Chapter 5
1.19 *bis*	in accordance with Article S14, to consider objections expressed by Administrations with respect to the Radio Regulations Board's Rules of Procedure relating to the application of RR 2674/S23.13 in order for the Bureau to modify its findings in accordance with the conclusions of the Conference;	
1.20	to consider the issues related to the application of Nos. **S9.8**, **S9.9** and **S9.17** and the corresponding parts of Appendix **S5** with respect to Appendices **S30** and **S30A**, with a view to possible deletion of Articles 6 and 7 of Appendices **S30** and **S30A**, also taking into consideration Recommendation **35 (WRC-95)**;	Chapter 5

1.21	consider report from the Radiocommunication Bureau on results of the analysis in accordance with Resolution **53 (WRC-97)** and take appropriate actions;	Chapter 5
2	to examine the revised ITU-R Recommendations incorporated by reference in the Radio Regulations which have been communicated by the associated Radiocommunication Assembly, in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;	Chapter 7, § 7.3
3	to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;	Not in scope of CPM
4	in accordance with Resolution **95 (WRC-97)**, to review the Resolutions and Recommendations of the previous Conferences with a view to their possible revision, replacement or abrogation;	Chapter 7, § 7.4
5	to review, and take appropriate action on, the report from the Radiocommunication Assembly submitted in accordance with Nos. 135 and 136 of the Convention (Geneva, 1992);	Not in scope of CPM
6	to identify those items requiring urgent actions by the radiocommunication study groups in preparation for the next world radiocommunication conference;	Not in scope of CPM
7	in accordance with Article 7 of the Convention (Geneva, 1992):	
7.1	to consider and approve the report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-97;	Not in scope of CPM
7.2	to recommend to the Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent Conference and on possible agenda items for future conferences,	Chapter 8

INTRODUCTION TO THE CPM REPORT TO WRC-2000

This CPM Report to WRC-2000 is provided to assist the ITU Member States and the Radiocommunication Sector Members who will be involved in the deliberations of the 2000 World Radiocommunication Conference. It represents the best information on technical, operational and regulatory/procedural issues relevant to the WRC-2000 agenda, available at the time of its preparation.

I.1 Origin and purpose of CPM-99

In accordance with Article 3, No.42 of the ITU Convention, the Council, at its 1998 session, resolved in Resolution 1130 (see Appendix I.1) to hold a World Radiocommunication Conference (WRC-2000) from 8 May to 2 June 2000 in Istanbul (Turkey) with an agenda modified with respect to the one proposed by WRC-97 as contained in Resolution 721 (WRC-97). These proposals have been accepted as a result of a consultation of the ITU Member States.

At the same time, the Council instructed the Director of the Radiocommunication Bureau " to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a report to WRC-2000,".

In addition, four topics have been included for consideration by the CPM following the decisions of the 1998 Plenipotentiary Conference:

- the evaluation of the administrative due diligence procedure for satellite networks adopted by WRC-97;
- the simplification of coordination and notification procedures for satellite networks;
- the role of the notifying administration in the case of an administration notifying on behalf of a named group of administrations; and
- the implementation of processing charges for satellite network filings and administrative procedures.

The 1997 Radiocommunication Assembly by its Resolution ITU-R 2 re-confirmed that preparatory studies for a WRC are to be carried out by a Conference Preparatory Meeting (CPM) and nominated Mr. T. Boe (Norway) as the Chairman of CPM-99, Mr. E. Behdad (Islamic Republic of Iran) and Mr. R. Barton (Australia) as the Vice-Chairmen.

Mr. T. Boe, due to other obligations, was no longer available to chair the CPM. Consequently, following consultations with both Vice-Chairmen of the CPM, it was proposed that Mr. R Barton act as Chairman of the CPM for WRC-2000.

All administrations of the ITU Member States and the Radiocommunication Sector Members were invited to participate in the preparation of the CPM Report to WRC-2000.

I.2 Organization of the ITU-R of the preparation for the conference

The Radiocommunication Assembly shall provide the necessary technical bases for the work of radiocommunication conferences. Organization of the conference preparatory work is shown in Figure I-1.

According to Resolution ITU-R 2-2, on the basis of contributions from administrations, the Radiocommunication Study Groups, the Special Committee, and other sources concerning the technical, operational and regulatory/procedural matters to be considered by radiocommunication conferences, the CPM prepares a consolidated report for such conferences.

The first Conference Preparatory Meeting (Geneva, 26-27 November 1997) organized preparatory studies for WRC-2000 and identified studies for the following WRC. A structure for the CPM Report to WRC-2000 was agreed together with a preparatory process, working procedures and a chapter structure. The meeting appointed a Rapporteur for each chapter to assist the Chairman in managing the development and flow of draft report contributions.

The meeting also decided that all appropriate regulatory/procedural studies on relevant agenda items would be carried out by the Special Committee on Regulatory/Procedural matters (SC) on the basis of proposals from the membership of the ITU and the relevant ITU-R Working Party/Task Group/Joint Rapporteur Group. According to Resolution ITU-R 38-1 the results of the studies shall be submitted as contributions to the work of the CPM in preparing its report to the relevant WRC.

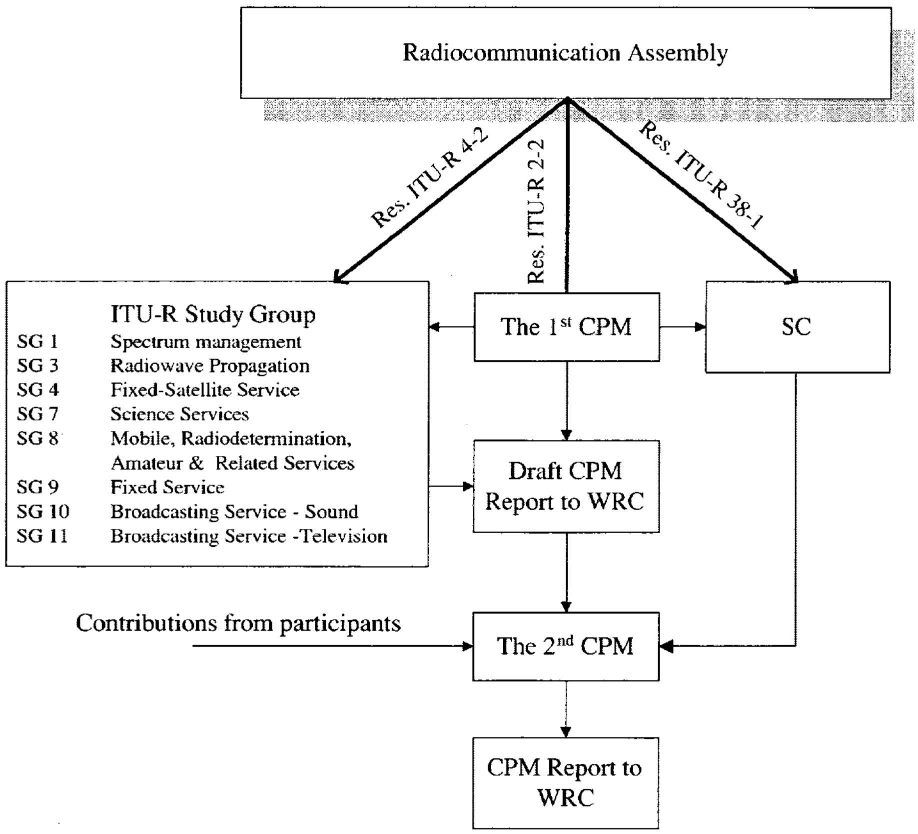

FIGURE I-1

Organization of the ITU-R conference preparatory work

The ITU-R preparations for WRC-2000 were concentrated in the following Task Groups and Working Parties (listed in the order of the Study Groups):

Study Group 1 chaired by Mr. R. Mayher (USA), TG 1/5 chaired by Mr. M. Dhamrait (UK), TG 1/6 chaired by Mr. G. Chan (Canada);

Study Group 3 chaired by Mr. D.G. Cole (Australia), WP 3J chaired by Mr. G. Brussaard (Netherlands), WP 3K chaired by Mr. E.J. Haakinson (USA), WP 3M chaired by Mr. M.P.M. Hall (UK);

Study Group 4 chaired by Mr. Y. Ito (Japan), WP 4A chaired by Mr. A.G. Reed (UK), WP 4-9S chaired by Mr. W. Rummler (USA), JTG 4-9-11 chaired by Mr. J. Leary (Japan);

Study Group 7 chaired by Mr. R.M. Taylor (USA), WP 7B chaired by Mrs. S. Taylor (USA), WP 7C chaired by Mr. L. Ruiz (France), JRG 7D-9D chaired by Mr. J. Miller (USA), WP 7D chaired by Mr. J.B. Whiteoak (Australia);

Study Group 8 chaired by Mr. E. George (Germany), WP 8B chaired by Mr. R.L. Swanson (USA), WP 8D chaired by Mr. T. Mizuike (Japan), TG 8/1 chaired by Mr. M.H. Callendar (Canada);

Study Group 9 chaired by Mr. M. Murotani (Japan), WP 9B chaired by Mr. A. Hashimoto (Japan), WP 9D chaired by Mr. G.F. Hurt (USA);

Study Group 10 chaired by Mr. A. Magenta (Italy), WP 10-11S chaired by Mr. R. Zeitoun (Canada);

Study Group 11 chaired by Mr. M. Krivosheev (Russia), WP 10-11S chaired by Mr. R. Zeitoun (Canada); and

Special Committee for Regulatory/Procedural Matters chaired by Mr. R.N. Agarwal (India).

I.3 Preparation of the CPM Report to WRC-2000

A draft CPM Report had been prepared by the Chapter Rapporteurs and the Chairmen of the relevant SGs/TGs/WPs on the basis of contributions from the relevant groups. The work was coordinated by Mr. R. Barton (Australia), Acting Chairman of CPM-99 and Mr. E. Behdad (Islamic Republic of Iran), Vice-Chairman of CPM-99. Staff of the Radiocommunication Bureau provided the required assistance. The draft CPM Report was distributed to all Members of the ITU and to members of the Radiocommunication Sector wishing to participate in the CPM as Document CPM 99-2/1.

The CPM-99 met in Geneva from 15 to 26 November 1999 under Chairmanship of Mr. R. Barton (Australia), Mr. E. Behdad, Vice-Chairman (Iran), assisted by Mr. A. Nalbandian, ITU Counsellor to consider the draft CPM Report (Document CPM 99-2/1), together with contributions from the ITU membership and additional material submitted by the Radiocommunication Bureau.

XXX delegates participated from **YY** ITU Member States, **ZZ** Radiocommunication Sector Members, including **UU** international organizations.

AAA contributions including the draft CPM Report (Document CPM99-2/1) and the SCPRM Report (Document CPM99-2/2) were submitted for consideration by the CPM-99.

At CPM-99 the contributions were attributed to Working Groups 1 – 7 for preparation of the final text for each Chapter according to the following adopted structure.

Chairman, CPM-99: Mr. R. Barton (Australia)
Secretary, CPM-99: A. Nalbandian (BR)

	Topic	Rapporteur	SC Assistant	BR Secretary
WG 1	**IMT-2000, maritime and aeronautical issues**	C. Van Diepenbeek (Netherlands)	R. Amero (Canada)	F. Leite
WG 2	**MSS and RNSS**	S. Jones (UK)	Not required	Y. Henri
WG 3	**Non-GSO FSS issues**	V. Rawat (Canada)	E. Davison (USA)	J. Li
WG 4	**Space science services and radio astronomy**	R. Jacobsen (Australia)	Not required	A. Matas
WG 5	**Appendices S30 and S30A**	E. Behdad (Iran)	F. Rancy (France)	G. Mesias
WG 6	**FS and FSS**	H. Kimball (USA)	A. Ashman (Australia)	L. Casado
WG 7	**Other matters**	N. Kisrawi (Syria)	F. Williams (USA)	K. Hughes

Chairman, SC Mr. R. Agarwal (India)
Secretary, SC Mr. P. Lundborg (ITU BR)

Editorial work was carried out by a Group chaired by Mr.L. Bourgeat, France and involving Prof. L. Barclay, United Kingdom, Sr. D. Celestino Menéndez, Spain and Mr. C. Langtry, BR Secretary.

The meeting was successful in approving the CPM Report to WRC-2000.

I.4 Presentation and structure of the Report

The Report is structured to follow the topics of the WRC-2000 agenda. Its outline was developed and approved by the first CPM at its meeting in November 1997. A cross-reference list is provided to facilitate finding specific topics within the framework of the WRC-2000 agenda.

The Report comprises eight Chapters and Annex.

Chapter 1 contains material relating to the **IMT-2000, maritime and aeronautical issues (agenda items 1.6, 1.7 and 1.18)**.

Chapter 2 contains material relating to the **Mobile-satellite and radionavigation-satellite services (agenda items 1.9, 1.10, 1.11 and 1.15 (1.15.1 – 1.15.3))**.

Chapter 3 contains material relating to the **Non-GSO FSS issues (Agenda item 1.13 (1.13.1 and 1.13.2))**.

Chapter 4 contains material relating to the **Space science services and radio astronomy (Agenda items 1.16 and 1.17)**.

Chapter 5 contains material relating to **RR Appendices S30 and S30A (Agenda items 1.19, 1.19bis, 1.20 and 1.21)**.

Chapter 6 contains material relating to the **Fixed and fixed-satellite services (Agenda items 1.4, 1.5, 1.8, 1.12 and 1.14)**.

Chapter 7 contains material relating to spurious emissions **(Agenda item 1.2)**, RR Appendix S7/28 **(Agenda item 1.3)**. It also contains information for action by WRC-2000 on the revised ITU-R Recommendations incorporated by reference in the Radio Regulations in accordance with Resolution on 28 (WRC-95) **(Agenda item 2)**, on Resolutions and Recommendations pertaining to issues arising from consideration of Resolution 95 (WRC-97) **(Agenda item 4)** and on **Resolutions of the ITU Plenipotentiary Conference, 1998**.

Chapter 8 contains material relating to the **Progress of studies for future conferences (Agenda item 7.2)**.

The Annex contains a list of the ITU-R Recommendations including certain draft new Recommendations which are referred to in the text of this Report. The final version of this list reflecting the decisions of the 2000 Radiocommunication Assembly will be prepared by the Radiocommunication Bureau and made available to the 2000 World Radiocommunication Conference.

NOTE 1 - As regards Agenda items 4 and 7.1 reports will be submitted by the Director, Radiocommunication Bureau to the WRC-2000.

NOTE 2 – The following terms used in Article S5:

"Designated"

"Identified"

"Intended for use"

"Available for use"

are used with apparently similar and/or different meanings. It was suggested that it would be useful to draw the attention of the Conference to this matter for its consideration.

APPENDIX I.1

RESOLUTION 1130

(APPROVED AT THE TWELFTH PLENARY MEETING)

AGENDA FOR THE WORLD RADIOCOMMUNICATION CONFERENCE (WRC-2000)

The Council,

noting

that Resolution 721 of the World Radiocommunication Conference (Geneva, 1997):

a) resolved to recommend to the Council that a world radiocommunication conference be held in Geneva in late 1999 for a period of four weeks;

b) recommended its agenda, and invited the Council to finalize the agenda and arrange for the convening of WRC-99 and to initiate as soon as possible the necessary consultation with Member States,

resolves

to convene a World Radiocommunication Conference (WRC-2000) in Istanbul (Turkey) from 8 May - 2 June 2000, with the following agenda:

1 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, taking account of the results of the 1997 World Radiocommunication Conference (WRC-97), and with due regard to the requirements of existing and future services in the bands under consideration, to consider and take appropriate action in respect of the following topics:

1.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, in accordance with Resolution **26 (Rev.WRC-97)**;

1.2 to finalize remaining issues in the review of Appendix **S3** to the Radio Regulations with respect to spurious emissions for space services, taking into account Recommendation **66 (Rev.WRC-97)** and the decisions of WRC-97 on adoption of new values, due to take effect at a future time, of spurious emissions for space services;

1.3 to consider the results of ITU-R studies in respect of Appendix **S7/28** on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services, and take the appropriate decisions to revise this Appendix;

1.4 to consider issues concerning allocations and regulatory aspects related to Resolutions **126 (WRC-97)**, **128 (WRC-97)**, **129 (WRC-97)**, **133 (WRC-97)**, **134 (WRC-97)** and **726 (WRC-97)**;

1.5 to consider regulatory provisions and possible additional frequency allocations for services using high altitude platform stations, taking into account the results of ITU-R studies conducted in response to Resolution **122 (WRC-97)**;

1.6 issues related to IMT-2000;

1.6.1 review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary;

1.6.2 identification of a global radio control channel to facilitate multimode terminal operation and worldwide roaming of IMT-2000;

1.7 review of the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to protecting operational, distress and safety communications, taking into account Resolution **346 (WRC-97)**;

1.8 to consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service (FSS) networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz, including their coordination with other services allocated in these bands;

1.9 to take into account the results of ITU-R studies in evaluating the feasibility of an allocation in the space-to-Earth direction to the mobile-satellite service (MSS) in a portion of the 1 559-1 567 MHz frequency range, in response to Resolutions **213 (Rev.WRC-95)** and **220 (WRC-97)**;

1.10 to consider results of ITU-R studies carried out in accordance with Resolution **218 (WRC-97)** and take appropriate action on this subject;

1.11 to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions **214 (Rev.WRC-97)** and **219 (WRC-97)**;

1.12 to consider the progress of studies on sharing between feeder links of non-GSO MSS networks and GSO FSS networks in the bands 19.3-19.7 GHz and 29.1-29.5 GHz, taking into account Resolution **121 (Rev.WRC-97)**;

1.13 on the basis of the results of the studies in accordance with Resolutions **130 (WRC-97)**, **131 (WRC-97)** and **538 (WRC-97)**:

1.13.1 to review and, if appropriate, revise the power limits appearing in Articles **S21** and **S22** in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services;

1.13.2 to consider the inclusion in other frequency bands of similar limits in Articles **S21** and **S22**, or other regulatory approaches to be applied in relation to sharing situations;

1.14 to review the results of the studies on the feasibility of implementing non-GSO MSS feeder links in the 15.43-15.63 GHz in accordance with Resolution **123 (WRC-97)**;

1.15 issues related to the radionavigation-satellite service:

1.15.1 to consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments;

1.15.2 to consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the bands 1 215-1 260 MHz and 1 559-1 610 MHz;

1.15.3 to consider the status of allocations to services other than the radionavigation-satellite service (Nos. **S5.355** and **S5.359**) in the band 1 559-1 610 MHz;

1.16 to consider allocation of frequency bands above 71 GHz to the earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution **723 (WRC-97)**;

1.17 to consider possible worldwide allocation for the earth exploration-satellite (passive) and space research (passive) services in the band 18.6-18.8 GHz, taking into account the results of the ITU-R studies;

1.18 to consider the use of new digital technology for the maritime mobile service in the band 156-174 MHz and consequential revision of Appendix **18/S18**, taking into account Resolution **342 (WRC-97)**;

1.19 to consider the report of the inter-conference representative group (IRG) submitted by the Director of the Radiocommunication Bureau and determine the basis for replanning by the next conference so as to afford each country an amount of spectrum that permits the economical development of a broadcasting-satellite service system;

1.19*bis* in accordance with Article S14, to consider objections expressed by administrations with respect to the Radio Regulations Board's Rules of Procedure relating to the application of RR 2674/S23.13 in order for the Bureau to modify its findings in accordance with the conclusions of the Conference;

1.20 to consider the issues related to the application of Nos. **S9.8**, **S9.9** and **S9.17** and the corresponding parts of Appendix **S5** with respect to Appendices **S30** and **S30A**, with a view to possible deletion of Articles 6 and 7 of Appendices **S30** and **S30A**, also taking into consideration Recommendation **35 (WRC-95)**;

1.21 to consider the report from the Radiocommunication Bureau on results of the analysis in accordance with Resolution **53 (WRC-97)** and take appropriate actions;

2 to examine the revised ITU-R recommendations incorporated by reference in the Radio Regulations in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;

3 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;

4 in accordance with Resolution **95 (WRC-97)**, to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

5 to review, and take appropriate action on, the report from the Radiocommunication Assembly submitted in accordance with Nos. 135 and 136 of the Convention (Geneva, 1992);

6 to identify those items requiring urgent action by the radiocommunication study groups in preparation for the next world radiocommunication conference;

7 in accordance with Article 7 of the Convention (Geneva, 1992):

7.1 to consider and approve the report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-97;

7.2 to recommend to the Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent Conference and on possible agenda items for future conferences,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a report to WRC-2000,

instructs the Secretary-General

1 to make all the necessary arrangements, in agreement with the Director of the Radiocommunication Bureau, for the convening and holding of the Conference;

2 to communicate this Resolution to concerned international and regional organizations.

CPM Report to WRC-2000

CONTENTS

CHAPTER 1

IMT-2000, maritime and aeronautical issues

(WRC-2000 agenda items 1.6, 1.7 and 1.18)

CONTENTS

IMT-2000, maritime and aeronautical issues

1.1 Agenda item 1.6

"Issues related to IMT-2000"

§ 1.1 is subdivided into 3 parts. Part A contains a general introduction to IMT-2000. Part B describes the spectrum requirements for IMT-2000, subdivided into part B.1 relating to the terrestrial component and part B.2 relating to the satellite component. Part C provides information to the readers on agenda items 1.6.1 and 1.6.2.

Part A - General introduction to IMT-2000

International Mobile Telecommunications-2000 (IMT-2000) is the ITU vision of global mobile access in the 21st century. Scheduled to start service around the year 2000 subject to market and other considerations, IMT-2000 is an advanced mobile communications concept intended to provide telecommunications services on a worldwide scale regardless of location, network, or terminal used. Through integration of terrestrial mobile and mobile-satellite systems, different types of wireless access will be provided globally, including services available through the fixed telecommunication networks and those specific to mobile users. IMT-2000 proposes a range of mobile terminal types, linking to terrestrial and/or satellite-based networks, and the terminals may be designed for mobile or fixed use.

The key features of IMT-2000 are:

a) high degree of commonality of design worldwide;

b) compatibility of services within IMT-2000 and with the fixed network;

c) high quality;

d) small terminals for worldwide use;

e) worldwide roaming capability;

f) capability for multimedia applications and a wide range of services (e.g. video-teleconferencing, high speed Internet, speech and high rate data).

As the ITU provides the best means of ensuring that IMT-2000 will meet the telecommunications needs of all regions across the world, the ITU-R and ITU-T Sectors are developing a set of interdependent Recommendations pursuant to IMT-2000.

At WARC-92, 230 MHz of spectrum[1] was identified for FPLMTS[2] via a provision (No. **S5.388**) in the Radio Regulations (RR). However, due to the tremendous growth in mobile communications since then, and the demand for wideband multimedia capability, the expected demand for additional IMT-2000 spectrum after the initial deployment must be considered.

---

[1] This frequency spectrum was identified based on calculations that are now documented in Recommendation ITU-R M.687-2.

[2] IMT-2000 was formerly known as FPLMTS (Future Public Land Mobile Telecommunications Systems).

WRC-97 decided that WRC-2000 should review the spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that "... there is an urgent need to provide spectrum for the terrestrial component".

In addition, WRC-97 decided that WRC-2000 should address agenda item 1.6.2, "the identification of a global radio control channel, to facilitate multimode terminal operation and worldwide roaming of IMT-2000". Resolution **212 (Rev.WRC-97)**, originally devised at WARC-92, summarizes the developmental, spectrum, and regulatory issues pertinent to IMT-2000.

Part B - Spectrum requirements for IMT-2000

In line with continuing technological advancements, more and more users will demand more and more capabilities from mobile services. Future mobile services must support not only speech but also a broad range of new telecommunication services that will serve a wide range of applications, as described in Recommendation ITU-R M.816. Bearer services supporting applications such as multimedia, internet access, imaging and videoconferencing will be needed in IMT-2000.

Forecasts of the spectrum requirements of the terrestrial and satellite components of IMT-2000 have been developed in Report ITU-R M.[IMT.SPEC]: "Spectrum requirements for IMT-2000". This Report uses expected market forecasts and assumptions on the operations of IMT-2000, for different environments and services, to determine the projected overall and additional spectrum requirements for IMT-2000.

For technical reasons (for instance propagation factors and terminal design), consideration of the additional spectrum requirements for IMT-2000 have focused on the same general frequency range as the original spectrum identified for IMT-2000; that is, below 3 GHz. For higher data rates, and where the user is stationary or nearly stationary, it may be desirable to utilize frequency bands above 3 GHz.

Part B.1 - Terrestrial component

Spectrum requirements for the terrestrial component of IMT-2000 were estimated in the CCIR Report to WARC-92, and those calculations are now documented in Recommendation ITU-R M.687-2. The estimation of a minimum requirement of about 230 MHz was the basis for the WARC-92 decision to identify spectrum in No. **S5.388**. At the time, speech services were considered to be the major source of traffic, and only low data rate services were additionally considered. Furthermore, usage of the mobile services has increased substantially since 1992, and has overtaken the estimations of that time.

Since WARC-92, the market for personal communications has expanded significantly, and, as well, it has become apparent that data applications, in particular multimedia applications, would play a major role in mobile radiocommunication services in the 2000-2010 time-frame. This will create a requirement for additional spectrum for IMT-2000 in the latter portion of the decade. Data rates up to 2 Mbit/s are anticipated in IMT-2000 Phase 1. The total spectrum requirement for terrestrial mobile services, calculated according to the methodology in Report ITU-R M.[IMT.SPEC], has assumed services with bit rates up to 2 Mbit/s only.

Report ITU-R M.[IMT.SPEC] concludes that there is a forecasted need for 160 MHz of additional spectrum for the terrestrial component of IMT-2000, beyond the spectrum already identified in No. **S5.388** and beyond the spectrum used in the three Regions for first and second generation mobile systems.

In calculating this forecasted spectrum need for geographical areas where the traffic is the highest, Report ITU-R M.[IMT.SPEC] applies the detailed methodology provided in Recommendation ITU-R M.1390 to the expected deployment of mobile systems in the three Regions for the year 2010.

The forecast used in Report ITU-R M.[IMT.SPEC] is a composite of information submitted in 1998 to ITU-R by several administrations from the three Regions.

Because IMT-2000 will provide high data rate services in addition to those services that are already provided by second generation mobile systems, it was not considered feasible to delineate in the forecasts IMT-2000 usage from existing systems' usage. Report ITU-R M.[IMT.SPEC] notes that these new services may have asymmetrical spectrum requirements. To determine the additional IMT-2000 terrestrial component spectrum requirement in the year 2010, it is necessary to subtract not only the spectrum already identified in No. **S5.388** for terrestrial IMT-2000, but also the spectrum used for first and second generation mobile systems from the total forecasted terrestrial mobile spectrum requirement. This is summarized in Table 1-1 below. There are some countries with different amounts of existing spectrum.

TABLE 1-1

Forecasted requirements for terrestrial spectrum

Region	**Total forecasted requirement for terrestrial mobile spectrum for the year 2010 (MHz)**	**Identified total for terrestrial mobile spectrum (including No. S5.388 IMT-2000 spectrum) (MHz)**	**Forecasted additional requirement for IMT-2000 terrestrial component spectrum for the year 2010 (MHz)**
Region 1	555	395	160
Region 2	390	230	160
Region 3	480	320	160

NOTE - The figures in the table above represent the requirement in those geographic areas where the traffic is the highest.

It is apparent that the frequency bands identified in No. **S5.388** are not likely to be used in a harmonized way globally in the short term due to the use of parts of this spectrum by pre-IMT-2000 systems in some countries. This is also the case at some other frequency bands (e.g. 800/900 MHz, and 1 800 MHz) where some countries will not make spectrum available for IMT-2000 before the long term, as it is used for first or second generation cellular systems with high level of investments, considerable amounts of traffic and different frequency plans. This therefore complicates the adoption of harmonized frequency plans (same uplink/downlink bands, duplex separation etc.) in these parts of the spectrum. Due to the need of having some globally harmonized frequency plans to ease roaming, it is particularly important to identify some additional spectrum for IMT-2000 where there is a reasonable chance of achieving a common frequency plan worldwide.

The spectrum forecasts are based on IMT-2000 traffic estimates up to the year 2010. The frequency bands for IMT-2000 would need to be identified for deployment well in advance of the year 2010 to allow adequate time for administrations to conduct domestic consultations, to license new radio systems, to transition, where required, existing systems from the affected bands and to deploy advanced mobile applications in the context of IMT-2000.

Part B.2 - Satellite component

The Report of the CPM to WRC-95 indicated that a total allocation for MSS of between 2 x 75 MHz and 2 x 150 MHz would be required by 2005 (Chapter 2, part A.2, § 3). Two years later, the Report of the CPM to WRC-97 indicated that 2 x 250 MHz would be necessary by 2010 (§ 4.2.6). A large number of satellite systems have been published in advance by ITU for the MSS frequency bands between 1 and 3 GHz; more than 150 systems in the 1.5/1.6 GHz bands, more than 50 systems in the 1.6/2.4 GHz bands, almost 100 systems in the 2 GHz band and about 75 systems in the 2.5/2.6 GHz bands. Some of these systems have been filed in more than one of the bands. It is expected that some systems will not be implemented due to financial or other reasons. Nevertheless, the number of filings demonstrate the very large interest in providing MSS in the 1-3 GHz range.

Report ITU-R M.[IMT.SPEC] concluded that there is a forecasted need for mobile-satellite spectrum as shown in Table 1-2. In calculating this spectrum need, Report ITU-R M.[IMT.SPEC] applies the detailed methodology provided in Recommendation ITU-R M.1391 to traffic estimates on the future demand for mobile satellite communications. The total MSS spectrum requirement is larger than that for the satellite component of IMT-2000 alone (see Table 1-2 and in the Introduction to Chapter 2).

TABLE 1-2

Forecasted requirements for global mobile-satellite spectrum, including IMT-2000 satellite component (MHz)

	Year 2005	**Year 2010**
IMT-2000 (satellite component)	2 x 31.5	2 x 67
Total MSS (including IMT-2000 satellite component)	2 x 123	2 x 145

NOTE - The figures in the table above represent the requirement in those geographic areas where the traffic is the highest.

In the various Regions, consideration should be given to the existing spectrum assigned for pre-IMT-2000 MSS services. Because the "Total MSS" spectrum calculation includes both pre-IMT-2000 and IMT-2000 services, a subtraction of the existing satellite spectrum allocated to the pre-IMT-2000 services must be performed to determine the additional satellite spectrum required for the IMT-2000 satellite component in the years 2005 and 2010. This subtraction has not been done in Report ITU-R M.[IMT.SPEC], due to the variation across Administrations of the spectrum allocated to pre-IMT-2000 satellite services.

Part C - Detailed information on agenda items 1.6.1 and 1.6.2

1.1.1 Agenda item 1.6.1 - terrestrial component

"review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary"

1.1.1.1 Spectrum vision for IMT-2000 terrestrial component

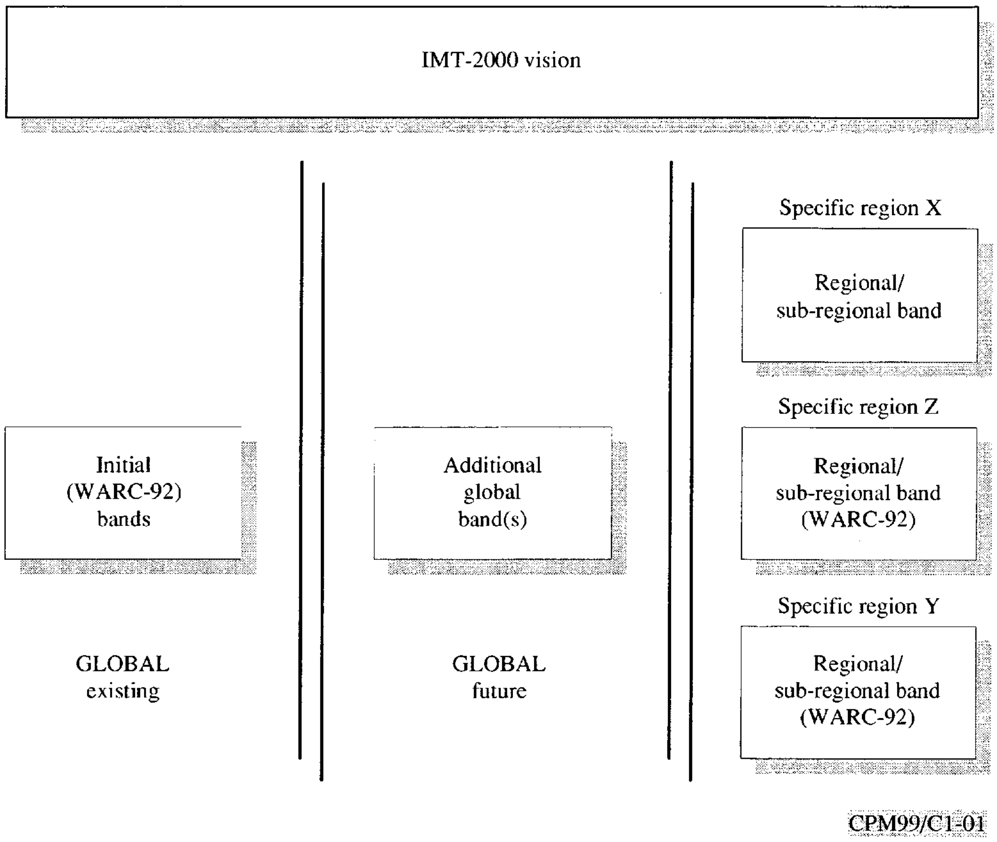
As explained in part B.1, there is a projected requirement for additional spectrum beyond that identified in No. **S5.388**. Although highly desirable it must be recognized that it will be difficult to find a global band or bands to meet the total additional spectrum demand. It may however be feasible to find a portion of this total demand on a global basis and the remainder on a regional basis. The concept in Fig. 1-1 provides a possible solution for a flexible use of spectrum for IMT-2000.

It is desirable to meet the projected IMT-2000 spectrum requirement of an additional global 160 MHz, as concluded in the studies undertaken in ITU-R, by identifying a limited number of contiguous global bands. This will reduce the cost, size and complexity of IMT-2000 terminal and network equipment and deployment, and provide the economies of scale for the mass market.

Equipment manufacturers recommend that administrations should not rely on future, possibly costly, technological advancements (e.g. multimode, multiband reconfigurable or fully digitized "software" radios, and adaptive antennas) to provide sufficient spectrum management flexibility and address the difficulties caused by band fragmentation, in order to offer global services without global spectrum. Manufacturers also considered that to do so may lead to unnecessary delay in implementing global services and result in roaming complications for customers, manufacturers and operators.

The need for additional spectrum for IMT-2000 may be met either from those bands already allocated to the mobile service or from new allocations to the mobile service or both, taking into account ITU-R studies and the needs of existing radio services. In considering a new allocation to the mobile service, account should be taken of sharing constraints associated with the current and potentially future uses of the services currently allocated.

FIGURE 1-1
Spectrum vision



Existing frequency bands allocated to the mobile service in which first or second generation mobile systems are in operation could be used for IMT-2000, via evolution. Indeed, because most existing mobile system technologies are already deployed in a variety of frequency bands, it is likely that first and second generation mobile system operators will eventually wish to implement IMT-2000 technology. This assumes that IMT-2000 meets operators' marketplace needs and provides an evolution path that facilitates implementation from pre-IMT-2000 systems. Providing compatibility between the frequency plans of first and second generation systems and those of future IMT-2000 systems will allow operators to evolve their networks without service disruption or imposing an unnecessary cost burden on network operators while minimizing possible interference.

Therefore, frequency bands used for first and second generation systems are natural candidates for IMT-2000 extension. However, as pointed out in part B.1, in some countries these bands will be made available for IMT-2000 only in the long term. In addition, these bands are not harmonized worldwide, and the timing of introduction of IMT-2000 systems in these bands will vary amongst countries, making it difficult to implement a single frequency plan on a global basis.

Any provision of IMT-2000 spectrum at WRC-2000 should be based on meeting the estimated spectrum requirement for geographic areas where the traffic is the highest, so that administrations which are expecting to have such requirements can adequately meet their projected IMT-2000 spectrum needs. However, it should be recognized that some administrations may not be able to, nor need to implement all of the IMT-2000 spectrum requirements on a national level, in the projected time-frame, owing to the structure of their own national market and the needs of other services in their countries. In such cases, in order to facilitate global operation of IMT-2000 it would be possible to consider identifying those portions of the IMT-2000 bands which can be globally harmonized so that administrations will be able to give first consideration to the use of those global bands.

It is most likely that the spectrum identified for IMT-2000 will consist of initial spectrum and additional frequency bands, which should be made available on a global basis to the maximum extent possible.

Initial (WARC-92) bands (1 885-2 025 MHz and 2 110-2 200 MHz): These initial bands are defined in No. **S5.388** where initial deployment of IMT-2000 systems could preferably be made. These are the bands currently identified in the RR for use by all administrations wishing to implement IMT-2000. Many countries are transitioning existing services in this spectrum and have planned introduction of IMT-2000. However, some Administrations may deploy IMT-2000 systems through an evolutionary process in bands other than those defined in No. **S5.388** (see Fig. 1-1).

Additional global bands: These bands are envisaged as worldwide bands for IMT-2000. Additional global bands are intended for the traffic demand which could not be accommodated in the initial bands. It would be desirable that the expansion of traffic estimated for 2010 could be absorbed by these bands. At least a portion of the global band(s) could be used in a harmonized way to facilitate global roaming (see Fig. 1-1).

Regional and subregional bands[3]: These additional bands may differ in frequency range and size from region to region. Such bands could be used as an overflow band for regions where higher capacity is needed, because of high population density and high penetration rate regarding mobile communications or for fixed applications using IMT-2000 standards. To promote the global concept of IMT-2000, these bands should be identified, as far as possible, as an exception and not as a rule (see Fig. 1-1).

1.1.1.2 Summary of technical and operational studies

a) List of relevant ITU-R Recommendations addressing sharing studies that are relevant to this agenda item

Sharing between IMT-2000 and other services: Recommendations ITU-R M.687-2 and ITU-R M.1036-1;

Sharing between space research, space operations or earth-exploration services and the mobile service: Recommendation ITU-R SA.1154;

Sharing between radionavigation and other services: Recommendation ITU-R M.[RAD.PROC];

Performance characteristics and operational conditions for HAPS providing IMT-2000: Recommendation ITU-R M.[IMT.HAPS].

---

[3] Regional and subregional bands relate to bands not identified globally, but rather to bands that are available either in one or more of the ITU Regions 1, 2 or 3, or in a part of an ITU Region only.

b) List of ITU-R Recommendations containing interference protection criteria and operational and technical characteristics that directly address the candidate bands for additional IMT-2000 spectrum (§ 1.1.1.3.3)

- Radiodetermination service: Recommendation ITU-R M.[RAD.CHAR2];
- Radio astronomy service: Recommendation ITU-R RA.769-1;
- Fixed service: Recommendation ITU-R F.758-1.

c) Additional relevant technical information

A number of the ITU-R Recommendations contain information on interference protection criteria and other information that, while not directly addressing potential IMT-2000 spectrum usage, may be useful for IMT-2000 sharing, evolution of first and second generation to IMT-2000, technical and operational studies:

- Radio astronomy service: Recommendation ITU-R RA.1031-1;
- Fixed service: Recommendations ITU-R F.1242, F.1098-1, F.1243, F.283-5, F.382-7, F.701-2, F.759, F.389-2, F.755, F.758-1, F.1334, F.1094-1, F.1241, F.1331, F.1245, F.1336 and F.699-4;
- Broadcasting service*: Recommendations ITU-R BT.1368-1, BT.417-4, BT.798-1, BT.655-1 and ITU-R IS.851-1;
- Broadcasting-satellite service (sound): Recommendation ITU-R BO.1130-1;
- Mobile service: Recommendation ITU-R M.1040 and draft new Recommendation ITU-R M.[8B/XA];
- Amateur service: Recommendation ITU-R M.1044;
- Earth exploration-satellite, space research and meteorological aids services: Recommendations ITU-R SA.1016, SA.1027-2 and SA.1157;
- Radiodetermination service: Recommendations ITU-R M.1313, M.629, M.[RAD.CHAR3] and M.[RAD.CHAR4];
- Evolution to IMT-2000: Recommendations ITU-R M.1308, M.1033 and M.1073.

1.1.1.3 Analysis of the results of studies

Limited sharing studies conducted to date within ITU-R indicate that IMT-2000 systems generally cannot share spectrum in the same geographical area with other radio operations in the mobile, mobile-satellite and other radio services. Use of spectrum on a co-channel basis with other radio operations may be feasible only through geographic separation. Nevertheless, it is recognized that the frequency bands most suitable for IMT-2000 are already heavily utilized by other operations in some geographic areas. It would be desirable for ITU Member States and Sector Members to undertake studies, and submit them to the ITU prior to WRC-2000, to determine whether certain IMT-2000 applications (e.g. indoor) are able to share spectrum with other IMT-2000 applications (e.g. outdoor vehicular).

* In relation to the broadcasting service, ITU-R is performing studies to assess spectrum requirements for these services in the light of their transition to digital technology.

1.1.1.3.1 Relevant ITU-R sharing studies

Recommendation ITU-R M.687-2 contains the conclusions of studies relating to the possibilities for IMT-2000 to share with other operations in the mobile, mobile-satellite and other radio services. From these studies, IMT-2000 may be able to share band allocations with fixed and possibly other services only where there is suitable geographic separation (e.g. urban/rural) between operations, or where neither operation requires the total allocated bandwidth. The economic cost associated with sharing has not been included in these considerations. The IMT-2000 with adaptive channel assignment will greatly facilitate sharing and will simplify the introduction of IMT-2000 into bands currently used by other radio operations. The relative geographic separation will depend on detailed system parameters. However, it is emphasized that co-channel sharing between the fixed service and IMT-2000 requires adequate geographic separation. Considering these factors, any Recommendation of the ITU-R F-series on fixed service channelling arrangements for potential IMT-2000 frequency bands may be useful in determining how to facilitate IMT-2000 deployment in bands that are co-located to the fixed service.

No. **S5.391** emphasizes that high-density mobile systems shall not be introduced in the bands 2 025-2 110 MHz and 2 200-2 290 MHz. Regarding the use of these bands by space science service missions, the demand for access to these bands continues to grow for both developed and developing countries. Several years of extensive studies within ITU-R have led to the adoption of a number of Recommendations which provide a stable long-term sharing environment between the space science services on one side, and various fixed service systems and some specific mobile service systems on the other side. The results of these studies were considered by WRC-97 which prepared Recommendation **622 (WRC-97)** for consultation when considering any changes in the regulatory provisions in the 2 025-2 110 MHz and 2 200-2 290 MHz bands. Any change in the present regulatory status would affect all the systems currently sharing these bands. In view of the above and the continuing extensive use of these bands by space services over the entire bandwidth as well as the terrestrial services, the allocation status of these bands should not be changed.

In the band 2 290-2 300 MHz, there are currently around ten very sensitive earth stations operating in the deep space research service. This number is expected to increase by a factor of two in view of planned new deep space activities. Studies carried out in ITU-R have revealed that sharing on a geographical separation distance may be feasible but would involve large coordination distances (1 400 km for Zone C locations, 390 km for Zone A locations) and practical separation distances of approximately 400 km based on interference from a single transmitter. Interference from a large number of transmitters has not been studied yet but will increase required separation distances.

The large separation distances required to protect earth stations operating in the space research (deep space) service would impose significant constraints on IMT-2000 systems. IMT-2000 operations would not be possible in all geographical areas. An appropriate footnote may be required to assure protection and continued availability of the use of this band by the space research service.

Recommendations ITU-R M-series (§ 1.1.1.2 a)) contain technical and operational characteristics and protection criteria of radiodetermination systems for use when assessing the compatibility of these services with other services in frequency bands under consideration as candidate bands for IMT-2000 (§ 1.1.1.3.4). It is vital to note that the radionavigation service operating in these bands is a safety service as specified by No. **S4.10** and provides a safety of life function, therefore requiring special measures to ensure their freedom from harmful interference. Appropriate technical and operational characteristics are required to determine the feasibility of introducing new types of systems or services in the bands between 420 MHz and 3.4 GHz, in particular the band 2 700-2 900 MHz that is identified in this report as an IMT-2000 candidate band, used by radionavigation and meteorological radars. Because the radiodetermination and meteorological radars perform indispensable functions and because their missions have requirements for large bandwidths in particular frequency bands, it is necessary to show by comprehensive studies that potential reallocations of radiodetermination and/or meteorological radar allocations will not erode their ability to perform their essential functions.

Given the technical characteristics of the radionavigation, radiolocation and meteorological radars (e.i.r.p. in the order of 1 GW in some systems and the trend towards high duty cycles) and the need to operate in accordance with the protection criteria contained in the Recommendations ITU-R M-series referenced in § 1.1.1.2 c), sharing with IMT-2000 systems is considered to be feasible only when explicitly confirmed by ITU-R sharing studies.

Regarding High Altitude Platform Stations (HAPS)[4], preliminary studies based on certain assumptions concluded that co-channel sharing and coordination with other IMT-2000 services operating according to Recommendation ITU-R M.1036-1, appears feasible under certain circumstances using terrestrial coordination procedures where the HAPS employs high performance antennas, CDMA radio interface with FDD access formats, and metropolitan size coverage areas, where similar CDMA radio interface with FDD access formats are used in the ground-based terrestrial systems. HAPS systems can be designed using filters or guardbands that limit out-of-band emission levels in compliance with permissible interference levels of receiving mobile stations or mobile earth stations. Recommendation ITU-R M.[IMT.HAPS] provides minimum performance requirements for HAPS for operation within IMT-2000, together with methods to evaluate the impact of interference caused by transmission of these HAPS. The impact of IMT-2000 terrestrial systems on HAPS operation and the possibility of sharing between HAPS providing IMT-2000 and services other than fixed and mobile has not been studied.

1.1.1.3.2 Considerations on sharing and transitional arrangements for the IMT-2000 candidate bands

It is expected that the use of IMT-2000 mobile applications will be most prominent in urban areas. Fixed systems operating in possible IMT-2000 candidate bands in rural areas or in areas with sufficient separation distance from IMT-2000 service areas may not be impacted and may be able to share. Fixed systems operating in or near highly congested IMT-2000 service areas may be able to re-establish service in other bands (for example, see Recommendation ITU-R F.1098 for point-to-point fixed systems). It should be noted that the deployment of IMT-2000 systems will take place over a period of time, giving time for the affected systems to migrate to another band, if necessary.

In cases where there is concern about potential interference to space operations and space research systems in possible IMT-2000 candidate bands, practical mitigation techniques may be available. In addition, where aggregate interference problems are anticipated, space operations/research facilities could possibly migrate to other bands, noting this transition period could be significant. (See section 1.1.1.3.1, paragraph 2, NOTE - Reference to space science services includes space operations and space research.)

In certain countries, where frequency bands are used for aeronautical-mobile telemetry operations, and where aggregate interference to these systems from existing mobile and/or fixed systems, and/or IMT-2000 systems is of concern, it may be possible to develop operational and technical mitigation

[4] It should be noted that issues related to HAPS, other than those concerning IMT-2000, are to be considered by the WRC under agenda item 1.5 (see § 6.2 of this report).

measures to address the situation, or to consider migration of aeronautical-mobile telemetry systems to other bands.

In those cases where sharing is impossible (in particular for aeronautical and meteorological radars) the only way to solve the problem of implementing IMT-2000 would be transition of the existing services to other frequency bands.

Significant financial investment may be required for the migration of systems to other bands. In addition, considerable effort may be required to locate suitable spectrum for these systems. However, it should be noted that geographical sharing may minimize transition costs.

1.1.1.3.3 Relevant ITU-R studies on evolution of first and second generation systems to IMT-2000

Recommendation ITU-R M.1308 provides guidelines for developers of pre-IMT-2000 systems who intend to evolve their systems towards IMT-2000. ITU-R M.1308 does not directly address the selection of additional bands for IMT-2000. However, it presents important information about the ability of earlier generation systems to evolve/migrate to IMT-2000, the coexistence issues and compatibility between second and third generation systems, and the need for flexibility to provide for multi-environment, multimode, and multiband capabilities.

1.1.1.3.4 Candidate bands for additional IMT-2000 terrestrial spectrum

Possible candidate bands for additional terrestrial IMT-2000 spectrum are given in Table 1-3 below.

Further information regarding the use of these bands (and others) may be found in Report ITU-R M.[IMT.SURVEY].

TABLE 1-3

Possible candidate bands for the terrestrial component of IMT-2000

Frequency band **470-806** MHz
This band is allocated to the broadcasting service worldwide. In addition, the band is also allocated on a co-primary basis in Region 3 to the fixed and mobile services and in Region 1, 790-806 MHz is also allocated to the fixed service on a co-primary basis. This band is mainly used for analogue broadcasting at the present time. The introduction of digital television is planned in many countries. This will be accomplished by introducing digital transmission in the currently used channel spacing and this is expected to facilitate the implementation of other radio services, including mobile, over a period of time. A transition period of perhaps 10-15 years is foreseen during which both digital and analogue transmissions will be in parallel. One administration has already planned to allow non-broadcasting use of parts of this band (i.e. 698-746 MHz and 746-764/776-794 MHz), possibly for cellular mobile service.

The frequency band 606-614 MHz (or 608-614 MHz) is allocated to radio astronomy in several countries (Nos. **S5.304**, **S5.305**, **S5.306** and **S5.307**). Several terrestrial services are also allocated in various part of the bands (see also Nos. **S5.291** to **S5.302** and **S5.309** to **S5.316**). In particular, there is heavy use of the lower part of the band (470-520 MHz) by fixed and mobile applications in some countries.

Due to the nature of analogue television planning the vacant channels in specific areas have found widespread application of low-power services such as wireless microphones and biomedical telemetry.

In most countries, television channels are assigned on the basis of regional or bilateral agreements. Digital television plans have to be established and new regional or bilateral agreements made.

Studies have been initiated in ITU-R to establish the future spectrum requirements for digital broadcasting.

Advantages

Introduction of digital broadcasting (with better spectrum efficiency) in the band and the ultimate phase-out of analogue TV should allow future consideration of other services in spectrum not required for digital television. In the contrary case, where identification of harmonized spectrum would not be possible, harmonized frequency plans should be developed in the whole band allowing compatible operation of IMT-2000 independently from the different sub-bands made available in different countries.

Coordinated transitioning to digital TV might facilitate the possibility of identifying harmonized spectrum within this frequency range for IMT-2000.

Disadvantages

Parts of the band are already used in some countries by some other services and such use may continue.

In most countries, the availability of TV spectrum, following phasing out of analogue TV is uncertain. Furthermore, the phasing out of analogue TV will vary between countries and is not expected to occur in many countries until after the 2005-2010 time-frame.

It is expected that spectrum demands for TV broadcasting will be greater during the transitional period and possibly beyond, on account of parallel operation of these services.

Frequency band **806-960** MHz

This band is allocated worldwide to the fixed, mobile and broadcasting services on a co-primary basis, except that in Region 2 the allocations in the bands 890-902 MHz and 928-960 MHz are to the fixed and mobile services only, and in the band 902-928 MHz it is to the fixed service.

A large part of this band is currently used for mobile systems for both PMR and cellular. Timing of availability for IMT-2000 will vary in different countries, from short-term availability to longer-term availability for regulatory, economic and other reasons.

Cellular systems in this band are using various frequency plans such as:

824-849 MHz paired with 869-894 MHz

880-915 MHz paired with 925-960 MHz

810-828 MHz and 860-885 MHz paired with 915-958 MHz; 893-895 MHz paired with 838-840 MHz; and 843-846 MHz paired with 898-901 MHz.

In those countries currently using part of this band for analogue broadcasting (up to 862 MHz), the transition to digital broadcasting may allow future use of this spectrum for IMT-2000.

Different portions of this band are used in various countries for fixed, amateur and radiolocation services. Also, the frequency band 902-928 MHz is an ISM band in Region 2.

Due to the nature of analogue television planning the vacant channels in specific areas have found widespread application of low-power services such as wireless microphones and biomedical telemetry.

In most countries, television channels are assigned on the basis of regional or bilateral agreements. Digital television plans have to be established and new regional or bilateral agreements made. Studies have been initiated in ITU-R to establish the future spectrum requirements for digital broadcasting. In many countries, in particular in some developing countries, transition to digital broadcasting is envisaged to start in this frequency range. **Advantages** IMT-2000 could be introduced in some bands currently used by existing systems, such as cellular. The use of the same frequency bands for IMT-2000 can assist in the evolution of first and second generation cellular systems to IMT-2000. **Disadvantages** Parts of this band are already used in some countries by some other services and such use may continue e.g. TETRA, railway-GSM, television broadcasting, ancillary broadcasting services, radiolocation and tactical radio relay and fixed wireless access in rural areas. In countries where this band is currently used extensively for existing mobile services, availability of this band for IMT-2000 can only be made progressively in the longer term as existing use decreases. Time-scales for availability of this band for IMT-2000 may differ. Different band plans for existing cellular mobile systems are currently used in different countries. Administrations are likely to want to retain the same band plan for IMT-2000. If administrations decide to retain the same band plans, it is likely to be a barrier to achieve worldwide harmonization of band plans for IMT-2000. In some countries, the availability of TV spectrum following phasing out of analogue TV is uncertain. Furthermore, the phasing out of analogue TV might not occur in the 2005-2010 time-frame.
Frequency band **1 429-1 501** MHz
This band is allocated worldwide to the fixed and mobile services on a co-primary basis. The band 1 452-1 492 MHz is allocated worldwide on a co-primary basis to the broadcasting and broadcasting-satellite services. This band is used for fixed service (such as subscriber multi-access radios for backbone rural telecommunication service), mobile aeronautical telemetry and telecommand. **Advantages** In two countries in Region 3, in the long term, there is a possibility to introduce IMT-2000, based upon an existing second generation mobile system and by phasing out of other existing services in the bands 1 429-1 453/1 477-1 501 MHz. **Disadvantages** The present and planned usage for aeronautical mobile telemetry, FS and digital audio broadcasting, both terrestrial and satellite, may preclude its use for IMT-2000 in many parts of the world. In general, phasing out of existing services would have cost/operational implications.

Several countries in Region 3 have indicated to ITU-R their intention to launch satellite digital sound broadcasting services in the band 1 452-1 492 MHz in accordance with Resolution **528 (WARC-92)**. Being the only worldwide allocation, it provides opportunities to bring broadcasting services to large areas including under-served rural and remote communities. Due to the importance of this band to the international and national infrastructure of many countries, it may not be considered as a viable band for an additional global band for IMT-2000 and may have limited usefulness for IMT-2000.
Frequency band **1 710-1 885** MHz
This band is allocated worldwide to the fixed and mobile services on a co-primary basis. Large parts of this band are used in many countries for second generation mobile systems: 1 850-1 885 MHz: portion of the PCS band, 1 710-1 785 (mobile station transmit)/1 805-1 880 (base station transmit) MHz: GSM 1800, and 1 880-1 885 MHz: portion of the DECT band. Parts of this band are also used by other operations (fixed systems, license-exempt applications). The band 1 755-1 850 MHz is used in some countries for such services as air traffic control, telemetry (ground and airborne) and space operations (see No. **S5.386**). Timing of spectrum availability for IMT-2000 will vary in different countries, from short-term availability to longer-term availability for regulatory, economic and other reasons. **Advantages** As 2nd generation mobile systems have been implemented in this band in many countries, it is a natural candidate for IMT-2000 deployment in those countries, with availability varying from short term to long term. If this band were to be identified for IMT-2000, it is possible that a harmonized frequency plan could be developed for many countries, based upon the 2nd generation mobile systems plans e.g., 1 710-1 755 MHz paired with 1 805-1 850 MHz, with duplex directions as indicated above. Spectrum is contiguous with the currently identified IMT-2000 bands in footnote No. **S5.388**. **Disadvantages** The few countries using a different cellular plan in this band other than the PCS or GSM 1800 indicated above may want to retain their existing cellular band plan for IMT-2000, noting that it might still be possible for countries utilizing a different plan to implement a portion of the 1 710-1 755/1 805-1 850 MHz band. Part of the bands are already used in some countries by some other services and some administrations have indicated that such use may continue for the foreseeable future. One Region 2 and one Region 3 administration have indicated that the band 1 755-1 850 MHz is extensively used for fixed, mobile, including aeronautical mobile and space operations services and is not available for IMT-2000. Existing satellite uplink operations will make the utilization of the band 1 755-1 850 MHz for IMT-2000 difficult in some countries. Coordination of these sites has been completed in accordance with No. **S5.386** for several sites throughout the world.
Frequency band **2 290-2 300** MHz
This band is allocated on a worldwide basis to the fixed, mobile, and space research (deep space) services on a co-primary basis. About ten earth stations are used for deep space research worldwide. The number of earth stations is planned to increase up to 20 within the next decade.

Advantages In some countries, this band is part of the fixed service channel plan which covers the 2.1-2.3 GHz band. Some administrations intend to relocate the fixed service in order to make available the No. **S5.388** bands identified for IMT-2000. Therefore, this band could also be made available following relocation of the fixed service. Coordination with earth stations for deep space research is feasible for licensed applications, although the exact procedure needs to be defined. **Disadvantages** The size of this band is limited, particularly if guardbands are needed to protect adjacent services. Studies to address protection of earth stations for deep space research have indicated that large separation distances of the order of several hundred kilometres are required. IMT-2000 cannot be deployed around these stations. Some administrations have indicated that this band will not be available due to existing uses (space research and fixed services). Introduction of IMT-2000 will result in restrictions on future deployment of space research systems. The use of this band by license-exempt applications is not feasible.
Frequency band **2 300-2 400** MHz
The allocation is to the fixed and mobile services in all Regions on a co-primary basis. In Regions 2 and 3 there is also a primary allocation to the radiolocation service. The band 2 310-2 360 MHz is allocated to the broadcasting-satellite service (sound) in three countries. (See No. **S5.393**). This band is used for aeronautical mobile telemetry and fixed service applications including multipoint distribution systems. This band is allocated worldwide on a secondary basis to the amateur service. **Advantages** Some Region 3 administrations consider this band as a possible candidate for IMT-2000 extension. **Disadvantages** There are a variety of uses of this band throughout the world. Several countries use all or part of these bands extensively for aeronautical mobile telemetry, which is considered vital to support test flight. Telemetry applications cannot be relocated at higher frequencies for a number of reasons, e.g., inability to use directive antennas, increased propagation loss and possibility of non-visibility events. Therefore countries employing telemetry are unlikely to be able to make this band available for IMT-2000. Relocation of the fixed services may be difficult in some countries.
Frequency band **2 520-2 670** MHz
This band is allocated on a co-primary basis to the fixed and mobile (except aeronautical mobile), and broadcast-satellite services in all three Regions. FSS (s-E) is allocated in this band in Region 2 and parts of this band, 2 520-2 535 MHz (s-E) and 2 655-2 670 MHz (E-s) in Region 3. The MSS can also use parts of this band according to Nos. **S5.403** and **S5.420**; some parts of this band are allocated to the broadcasting-satellite service (sound) and complementary terrestrial broadcasting service on a primary basis according to No. **S5.418**. BSS services have been operating in several Region 1 and Region 3 countries for the last two decades, covering large areas in these Regions and MSS services are used in some Region 3 countries.

Satellite broadcasting in this band is used as a complementary broadcasting system of choice, by countries covering many island territories, with particular benefits under high rainfall conditions. This band is used for different services and applications in different countries e.g. for fixed, Electronic News Gathering (ENG)/Outside Broadcasting (OB), fixed wireless access and multipoint distribution applications. **Advantages** Where and when the existing services can be phased out, this band could contribute a significant portion of the required additional spectrum. Since existing BSS and MSS allocations can only be used in a limited way this should not preclude the identification of this band for IMT-2000 under similar provision as contained in No. **S5.388**. Geographical sharing (urban/rural) might facilitate the transition or even enable, in the longer term, remaining operation of other services. Many Region 1 administrations have indicated that they could make this band or portions of it available for the IMT-2000 terrestrial component. Some administrations expressed the view that their ENG and outside broadcast operations are typically tuneable over a large frequency range which may give some flexibility if introducing the terrestrial component of IMT-2000 in this band. **Disadvantages** In a number of countries this band is used for multipoint distribution systems (in some countries extensively) that have been deployed in urban as well as in rural areas. Licenses for this service have been recently granted for extended periods of up to 20 years. Phasing out of these services and BSS and MSS will therefore be very difficult for the foreseeable future. Therefore the use of these bands may be precluded for IMT-2000 in these countries. Some administrations expressed the view that their use of this band for ENG, outside broadcast applications and fixed wireless access backhaul networks would conflict with its use for the terrestrial component of IMT-2000.
Frequency band **2 700-2 900** MHz
This band is allocated, worldwide on a primary basis to the aeronautical radionavigation service (ARNS) and on a secondary basis to the radiolocation service. Meteorological radars can also operate in this band with equality to the ARNS, based on No. **S5.423**. This band is used extensively for radar systems in some countries (aeronautical radionavigation systems and meteorological radars). Unlike other bands in this table, this band is not currently allocated to the mobile service. Since the ARNS is a safety service, the appropriate sharing studies and impact assessment would have to be undertaken to ensure the necessary protection to this service. Initial sharing studies conducted to date have led to different conclusions. Some members support a sharing study between ARNS and meteorological radars and IMT-2000 systems in the 2 700-2 900 MHz band conducted in accordance with Recommendations ITU-R M.[RAD.PROC], [RAD.CHAR2], [IMT.RKEY] and [IMT.RSPC], and Recommendation ITU-R M.687. This initial study places the usability of this band by IMT-2000 systems into question. These members have the view that further comprehensive ITU-R studies are required before this band is considered for IMT-2000.

Some other members support a study that shows that sharing is technically feasible between radars in the ARNS and IMT-2000. This study addressed high traffic areas for IMT-2000, which could have adequate geographical separation from the radars. In addition to the geographical separation, the studies indicated that co-channel sharing would not be possible, and that a frequency separation of at least 5 to 10 MHz would be needed depending on the selectivity of the ARNS radar system.

Advantages

In some countries, a limited number of radar systems are deployed in this band and future usage is under consideration. Therefore, in countries where either existing usage can be phased out or usage is limited and geographical sharing with existing services is possible, this band could possibly be made available for IMT-2000.

Disadvantages

There is uncertainty about the potential impact that IMT-2000 operations would have on the existing aeronautical radionavigation and meteorological use of this band.

A number of administrations have indicated that this band is the primary band for air traffic control and primary airport surveillance radars as well as for meteorological radars. Some administrations as well as some intergovernmental organizations are of the view that the use of this band for aeronautical radionavigation and meteorological radars, at present low in some countries, is expected to increase. In addition, some administrations are of the view that this band will be unavailable for IMT-2000.

Airport surveillance and meteorological radars operating in this band are typically located in or near densely populated areas, where IMT-2000 (terrestrial) spectrum is most needed, which may preclude geographical sharing within some countries. In the view of some administrations IMT-2000 use of this band would lead to spectrum that is not globally available, which is inconsistent with the goals of IMT-2000.

Further ITU-R sharing studies between the potential use of this band by IMT-2000 and incumbent radar systems need to be undertaken.

Band(s) for further study

Some Region 3 countries have indicated their intention to study the allocation in the 3 000-3 400 MHz band, because of high existing usage of the frequency bands below 3 000 MHz in their countries.

Band(s) considered not suitable for IMT-2000

It should be noted that the bands 2 025-2 110/2 200-2 290 MHz are considered not suitable for IMT-2000 since they are and continue to be extensively used by space services as well as the terrestrial services.

1.1.1.3.5 HAPS in IMT-2000 systems operating in bands identified in No. S5.388

No. **S4.15A** limits transmission to and from HAPS to bands specifically identified in the Table of Frequency Allocations. So far, the only bands which are identified as such by No. **S5.552A** are 47.2-47.5 GHz and 47.9-48.2 GHz. The use of HAPS to provide IMT-2000 is therefore conditioned to the identification of the bands identified for IMT-2000 as available for use by HAPS. If such identification is undertaken, it should be limited to those bands currently identified in No. **S5.388.** This is because new bands to be identified for IMT-2000 under this agenda item may have to share with various services having primary and/or secondary allocations. Until now sharing has only been investigated in the existing bands with a primary focus on sharing the delivery of IMT-2000 applications by both terrestrial-based and HAPS-based systems. However, the sharing studies did not thoroughly address some existing applications, such as PCS, MMDS, etc. currently operating in the bands identified in No. **S5.388**.

As a land station in the land mobile service, a HAPS providing IMT-2000 is a base station (No. **S1.69**). There should be no difference between the notification of a HAPS providing IMT-2000 and a conventional base station. It appears that the items required in Annex 1 to RR Appendix **S4** for base stations provide sufficient information for administrations to evaluate the probability of interference according to Recommendation ITU-R M.[IMT.HAPS].

Recommendation ITU-R M.[IMT.HAPS] provides guidance to administrations evaluating the probability of interference from HAPS IMT-2000 systems. It provides a co-channel spectral power flux-density limit on HAPS emissions at an administration's borders. This limit is independent of the exact use of the band by the neighbouring administration. However, as this limit represents a trigger value for coordination purposes, this Recommendation also provides coordination distance at which the interference level is permissible, depending on the HAPS coverage area and on each of the possible uses of the band by the neighbouring administration.

HAPS providing IMT-2000 should not receive any notification or regulatory priority, such as No. **S11.26**, over existing or future IMT-2000 base stations. No. **S11.26** should not apply to the bands identified for IMT-2000.

However, it might be necessary to request the notification of HAPS for information purposes, in order to inform all administrations of assignments that potentially could cause interference.

1.1.1.4 Methods to satisfy the agenda item and their advantages and disadvantages

With regards to the identification of additional spectrum for IMT-2000 to satisfy the agenda item 1.6.1, it is considered that there are two methods. These methods are described below.

Method 1

Additional global or regional/subregional bands could be listed through footnotes in Article **S5**, with appropriate reference to Resolution **212 (Rev.WRC-97)**. The formulation of these footnotes for identification of additional spectrum for IMT-2000 could either be similar to No. **S5.388** or adopt the format of footnotes such as No. **S5.547**, which is used for identification of the High Density Fixed Systems (HDFS) bands.

One alternative in this method is to modify No. **S5.388** to include the additional global bands, and a new No. **S5.YYY** (see § 1.1.1.5.1) would be needed to include the additional regional/subregional bands; both footnotes should have a link to the revised version of Resolution **212 (Rev.WRC-97)** or a new Resolution.

Another alternative is to modify No. **S5.388** to reflect the revised Resolution **212 (Rev.WRC-97)** in combination with the addition of footnotes **S5.XXX** and **S5.YYY** (see § 1.1.1.5.1), specifying the additional global bands and the additional regional/subregional bands respectively, both footnotes having a link to the updated version of Resolution **212 (Rev.WRC-97)** or a new Resolution.

In both alternatives the different dates of availability for the additional IMT-2000 bands could be given in the revised version of Resolution **212 (Rev.WRC-97)** or in the new Resolution.

Advantages

- Having a footnote in the Table of Frequency Allocations for the IMT-2000 additional bands is consistent with the regulatory format adopted at WARC-92 to identify frequency bands for IMT-2000 in No. **S5.388.** The reference to IMT-2000 in the Table of Frequency Allocations highlights the use of these frequencies for IMT-2000 and could therefore facilitate the worldwide implementation of IMT-2000 and global roaming, without preventing administrations to allow other advanced mobile applications in these bands if they wish.
- The harmonization of IMT-2000 spectrum globally is an extremely important issue. There is preference to clearly indicate all IMT-2000 global and regional/subregional frequency bands in a footnote(s) in Article **S5** of the Radio Regulations.

Disadvantage

- This different regulatory format for IMT-2000 systems compared to other mobile systems or radio services which are not footnoted in the RR, could be misinterpreted as giving a different regulatory status to IMT-2000 compared with other systems.

Method 2

Additional global and regional/subregional bands could be listed in a new WRC Resolution or Recommendation, without any specific identification in a footnote to the RR. Different dates of availability for additional IMT-2000 bands could be given in this new WRC Resolution or Recommendation. Administrations may implement IMT-2000 systems in any appropriate frequency bands allocated to the mobile service, therefore footnotes in Article **S5** of the RR are not essential.

One alternative in this method is to maintain unchanged No. **S5.388** and Resolution **212 (Rev.WRC-97)** and to develop a new Resolution listing the additional frequency bands and their of availability.

Another alternative would be to suppress both No. **S5.388** and Resolution **212 (Rev.WRC-97)**, and to develop a new Resolution or Recommendation listing both the initial and additional frequency bands for IMT-2000 and their dates of availability.

Advantages

- Avoids misinterpretation of the regulatory status of IMT-2000 by disassociating any additional spectrum identification for IMT-2000 from the Table of Frequency Allocations.
- Similar to Method 1, the reference to IMT-2000 in a WRC Resolution or Recommendation highlights the use of these frequencies for IMT-2000 without preventing administrations to allow other advanced mobile applications in these bands if they wish.

Disadvantages

- Listing the additional IMT-2000 frequency bands in a new WRC Resolution or Recommendation, without a corresponding reference in a footnote in the Table of Frequency Allocations, gives a different regulatory format to the additional bands compared to the WARC-92 bands identified in No. **S5.388.**
- This might imply a different status between the existing spectrum identified at WARC-92 and the additional IMT-2000 bands. There is also the danger that the Resolution or Recommendation, if not referenced in a footnote, be disregarded by administrations. Furthermore, changing the regulatory format in this way might cause misconceptions that the worldwide implementation of IMT-2000 is becoming a lower priority than originally

envisaged. Although it is not unique, some administrations question whether a Resolution, which does not address a transitional measure, is appropriate without any reference in Article **S5**.

- Concerning HAPS, proposed changes to the RR are given in § 1.1.1.5.2.

1.1.1.5 Regulatory and procedural considerations

1.1.1.5.1 Regarding IMT-2000, exclusive of HAPS

Different methods to satisfy agenda item 1.6.1 are presented in § 1.1.1.4 above.

Some common regulatory provisions are required for the methods proposed whereas for some of the proposals additional specific regulatory provisions are needed. Additionally, there are a number of possible options available to satisfy the methods indicated in § 1.1.1.4 above:

- Specific regulatory provision will be needed for frequency bands not already allocated to the mobile service, in order to allocate them to the mobile service on a primary basis. Where bands are allocated to the mobile service on a primary basis, consideration needs to be given to the method of identifying these bands for IMT-2000, as indicated in § 1.1.1.4 above.
- It is possible that the additional IMT-2000 bands can be indicated either in a new Conference Resolution or Recommendation or through modification of Resolution **212 (Rev.WRC-97)**. This may lead to the suppression or modification of footnote No. **S5.388**.

If following the format of No. **S5.388**, the required footnotes could be structured as follows:

ADD S5.XXX *(Additional global bands for terrestrial IMT-2000)*: The bands [...] are intended for use, on a worldwide basis, by administrations wishing to implement International Mobile Telecommunications-2000 (IMT-2000). Such use does not preclude the use of these bands by other services to which these bands are allocated. The band should be made available for IMT-2000 in accordance with Resolution **212 (Rev.WRC-2000)** or a new Resolution.

ADD S5.YYY *(Additional regional/subregional bands for terrestrial IMT-2000)*: In [region XYZ/countries ...], the band [...] is also intended for use by administrations wishing to implement International Mobile Telecommunications-2000 (IMT-2000). Such use does not preclude the use of these bands by other services to which these bands are allocated. The bands should be made available for IMT-2000 in accordance with Resolution **212 (Rev.WRC-2000)** or a new Resolution.

1.1.1.5.2 Regarding HAPS

Concerning the possible implementation of HAPS in an IMT-2000 system, the following regulatory changes could be considered:

ADD S5.HHH In Regions 1 and 3, the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz, and in Region 2 the bands 1 885-1 980 MHz and 2 110-2 160 MHz, may be used by high altitude platform stations as base stations to provide IMT-2000. The minimum performance characteristics and operational conditions shall be as defined in Recommendation ITU-R M.[IMT.HAPS].

Though Recommendation ITU-R M.[IMT.HAPS] provides for specific pfd (SPFD) limits at the boundary of neighbouring administrations, unless agreed otherwise between the administrations concerned, it is considered that these matters will need to be adequately addressed in the regulatory texts to be adopted at WRC-2000.

If considered necessary, the WRC may decide to request notification of HAPS.

ADD S11.8A *g)* if it is a high altitude platform station.

For purposes of enabling HAPS operation in the bands identified in No. **S5.HHH**, No. **S11.26** should not apply to the bands identified for IMT-2000.

1.1.2 Agenda item 1.6.1 - satellite component

1.1.2.1 Spectrum vision for IMT-2000 satellite component

WRC-2000 agenda item 1.6.1 includes the satellite component since it is an integral part of IMT-2000, as indicated in Resolution **212 (Rev.WRC-97)**. There must be a viable and operational satellite component to enable IMT-2000 to achieve the objectives stated in Recommendation ITU-R M.687-2, particularly regarding true global coverage.

The IMT-2000 terrestrial component will not be able to provide global coverage, and large geographic areas will remain without terrestrial coverage. The satellite component will provide IMT-2000 services in these geographic areas. Of the population within terrestrial coverage, some IMT-2000 customers will travel for both business and pleasure, to areas without terrestrial coverage. The high penetration expected for IMT-2000 means that some customers will want communications and high mobility anywhere and everywhere they travel. It is only through the combination of IMT-2000 terrestrial and satellite components that true global coverage can be accomplished.

It is also important to note that regions where high terrestrial coverage is anticipated may not be the driving force for determining spectrum requirements for the satellite component of IMT-2000. Rather, the areas of low terrestrial coverage are likely to be the main drivers for satellite IMT-2000 spectrum.

Availability of global spectrum is particularly important for the satellite component. If global spectrum is not available, deployment costs could be prohibitive.

The spectrum vision developed for the terrestrial component in Fig. 1-1 in § 1.1.1.1 is also applicable to the IMT-2000 satellite component. The bands for the satellite component identified in Resolution **212 (Rev.WRC-97)** are 1 980-2 010 MHz and 2 170-2 200 MHz.

As the spectrum needed to support the IMT-2000 satellite component is discussed, it is useful to examine the situation of the 2 GHz MSS allocations identified by No. **S5.388** and Resolution **212 (Rev.WRC-97)** that are intended to be used by the IMT-2000 satellite component. Resolution **212 (Rev.WRC-97)** identifies the bands 1 980-2 010 MHz and 2 170-2 200 MHz for the satellite component of IMT-2000. However, the portion 1 980-1 990 MHz is not available in many countries in Region 2 for the MSS as per No. **S5.389B**. The MSS is also allocated in Region 2 to the 2 010-2 025 MHz and 2 160-2 170 MHz bands.

Non-IMT-2000 MSS systems are not precluded from using these allocations and are likely to do so, thereby reducing the amount of spectrum potentially available to support the IMT-2000 satellite component in this band. Sufficient frequency spectrum needs to be made available, in the year 2005-2010 time-frame, to allow for the possibility of competition.

An important question for WRC-2000 to decide is whether the provision of additional satellite IMT-2000 spectrum comes from frequency bands already allocated to the MSS or if new allocations to the MSS should be made for such purposes. Consideration should be given to identifying existing MSS allocations between 1 and 3 GHz for satellite IMT-2000 applications. It is foreseen that most of the MSS bands between 1 and 3 GHz could be used for IMT-2000 in the longer term. However, the requirement for spectrum for other types of MSS systems also needs to be taken into account.

An important factor when looking at spectrum for mobile-satellite systems is the system replacement and evolution. Satellite systems equipment ages and must ultimately be replaced; however, replacement of this equipment is inherently a long-term process and can be difficult to accomplish. Therefore, use of currently occupied MSS spectrum for future satellite IMT-2000 systems will require substantial planning, investment and coordination with the current operators.

It should be noted that, while future MSS systems will employ advanced techniques, resulting in greater spectrum efficiency than hitherto possible, this improvement has already been accounted for in the satellite spectrum requirements given in part B.2.

1.1.2.2 Summary of technical and operational studies

There are Recommendations listed under the terrestrial component (§ 1.1.1.2) which may also be relevant.

1.1.2.2.1 List of relevant ITU-R Recommendations

Recommendations ITU-R M.1141-1 and M.1142-1 contain or address sharing studies that are relevant to this agenda item.

1.1.2.2.2 Additional relevant technical information

Recommendations ITU-R F.1335 and M.1184 contain information on interference protection criteria and other information that, while not directly addressing potential IMT-2000 spectrum usage, may be useful for IMT-2000 sharing, technical and operational studies.

Other ITU-R Recommendations containing useful information and characteristics for the MSS are: ITU-R M.1091, M.1143-1 and M.1183.

1.1.2.3 Analysis of the results of studies

1.1.2.3.1 Relevant ITU-R sharing studies

It is noted that agenda item 1.9 of WRC-2000 deals specifically with the frequency band 1 559-1 610 MHz (Resolution **220 (WRC-97)**) and 1 675-1 710 MHz (Resolution **213 (Rev.WRC-95)**), which is addressed in § 2.2 of this report. These two bands are not considered further in this section.

1.1.2.3.2 Possible candidates for additional satellite IMT-2000 bands

Consideration on candidates for additional IMT-2000 satellite bands has revealed that the following bands are potential candidates for IMT-2000 (see Table 1-4).

Further information regarding the use of these bands (and others) may be found in Report ITU-R [IMT.SURVEY].

TABLE 1-4

Possible candidate bands for the satellite component of IMT-2000

Frequency bands **1 525-1 559/1 626.5-1 660.5** MHz
These bands are allocated to the MSS on a global basis. 1 525-1 535 MHz is also allocated on a co-primary basis to the space operation service (s-E). 1 525-1 530 MHz is also allocated in Regions 1 and 3 to the fixed service on a co-primary basis. 1 660-1 660.5 MHz is allocated on a worldwide basis to the radio astronomy service on a co-primary basis. In the bands 1 525-1 559/1 626.5-1 660.5 MHz, MSS systems have been in operation for more than ten years. With an increasing number of new operators and increasing demand for MSS services, the bands are now rapidly approaching saturation, as is evident from the continuing regional multilateral coordination activities. Safety communications have priority in the bands 1 530-1 544/1 626.5-1 645.5 MHz as per No. **S5.353A**, and in the 1 545-1 555/1 646.5-1 656.5 MHz band, as per No. **S5.357A**. The bands 1 544-1 545/1 645.5-1 646.5 MHz are limited to distress and safety communications according to Article **S31**. **Advantages** Although the systems currently operating in these bands were state-of-the-art when launched, technological advancements will continue to lead to new systems being even more spectrum efficient. Hence, as the current MSS systems are eventually replaced by new systems, potentially including satellite IMT-2000 systems, such systems may be able to use these bands. These bands are allocated to the MSS on a global basis. **Disadvantages** The implementation of the satellite component of IMT-2000 in these bands will have to take into account the possibility of spectrum congestion (see Chapter 2, part A, § 5). Portions of the band 1 525-1 559 MHz and 1 626.5-1 660.5 MHz are subject to safety communications constraints. Deployment of IMT-2000 in these bands must take into account that usage in the sub-band 1 544-1 545/1 645.5-1 646.5 MHz is limited to distress and safety communications.
Frequency bands **1 610-1 626.5/2 483.5-2 500** MHz
These bands are currently allocated on a global basis to the MSS. The band 1 610-1 626.5 MHz is also allocated worldwide to the aeronautical radionavigation service on a co-primary basis. The band 1 610-1 626.5 MHz is in Region 2 and and some Regions 3 countries also allocated on a co-primary basis to the radiodetermination-satellite service. The sub-band 1 610.6-1 613.8 MHz is also allocated in all three Regions to the radio astronomy service on a co-primary basis. The band 2 483.5-2 500 MHz is also allocated worldwide on a co-primary basis to the fixed and mobile services. This same band is also allocated to the radiolocation service on a co-primary basis in Regions 2 and 3, and in Region 2 and some Region 3 countries the band is also allocated on a co-primary basis to the radiodetermination-satellite service. These bands are used or planned to be used by several mobile satellite PCS systems using non-GSO satellites. **Advantages** These bands are currently allocated to the MSS on a global basis. **Disadvantages** These bands are being used by MSS systems that have either just started or are about to start operation. The bands may only be available for satellite IMT-2000 in the longer term.

Frequency bands **2 500-2 520/2 670-2 690** MHz
The bands are allocated to the MSS on a global basis. Both bands are also allocated on a worldwide co-primary basis to the fixed and mobile services, and in Regions 2 and 3 the bands are also allocated on a co-primary basis to the fixed-satellite service. The allocation of these bands to the MSS is effective 1 January 2005. (No. **S5.414** and No. **S5.419**) These bands are used for different terrestrial applications in different countries. Studies that have been conducted within ITU-R have established pfd and FDP trigger values for coordination between the MSS and the fixed service in the band 2 500-2 520 MHz in the space-to-Earth direction. **Advantages** If other services can be phased out, these bands would contribute a significant portion of the required satellite IMT-2000 spectrum. These bands are already allocated to the MSS on a global basis and used or planned for use by the MSS in some countries. Making these bands available for satellite IMT-2000 would reduce the need for any additional MSS allocations to satisfy the satellite IMT-2000 spectrum requirements. Some administrations expressed the view that their ENG and outside broadcast operations are typically tuneable over a large frequency range which may give some flexibility if introducing the satellite component of IMT-2000 in this band. **Disadvantages** In a number of countries these bands are used for multipoint distribution systems (in some countries extensively) that have been deployed in urban as well as in rural areas. Licenses for this service have been recently granted for extended periods of up to 20 years. Phasing out of these services will therefore be very difficult for the foreseeable future and therefore may preclude its use for IMT-2000 in these countries. Some administrations expressed the view that their use of this band for ENG and outside broadcast applications would conflict with its use for the satellite component of IMT-2000.

According to Nos. **S5.403** and **S5.420**, the bands 2 520-2 535 MHz and 2 655-2 670 MHz may be used for MSS (except AMSS, see also Nos. **S5.515A** and **S5.420A**) for operation within national boundaries, and subject to agreement obtained under No. **S9.21**. These bands have been identified as possible candidate bands for the terrestrial component of IMT-2000, and are therefore not identified as suitable for satellite component. However, it is envisaged that these bands may be used for MSS in some areas, where the demand for satellite services is high.

The frequency bands 2 010-2 025 MHz (E-s) and 2 160-2 170 MHz (s-E) are allocated to the MSS, but only in Region 2. These bands are not available to the MSS in Regions 1 and 3. These bands are included in the spectrum identified in No. **S5.388** for IMT-2000, and are adjacent to the global 2 GHz MSS allocations. However, these bands are not global MSS bands and their status as part of the satellite component of IMT-2000 is not addressed in Resolution **212 (Rev.WRC-97)**.

1.1.2.4 Methods to satisfy the agenda item and their advantages and disadvantages

The spectrum requirements given in part B.2 might not be fulfilled in the existing MSS allocations and it is noted that other proposals will be considered by WRC-2000 under Resolution **220**, **(WRC-97)**, Resolution **213 (WRC-95)** and agenda item 1.9.

With regards to the identification of additional spectrum for IMT-2000 to satisfy the agenda item 1.6.1, it is considered that there are two methods. These methods are described below.

Method 1

Additional global or regional/subregional bands could be listed through footnotes in Article **S5**, with appropriate reference in Resolution **212 (Rev.WRC-97)**. The formulation of these footnotes for identification of additional spectrum for IMT-2000 could either be similar to No. **S5.388** or adopt the format of footnotes such as No. **S5.547**, which is used for identification of the High Density Fixed Systems (HDFS) bands.

One alternative in this method to modify No. **S5.388** to include the additional frequency bands; this footnote should have a link to the revised version of Resolution **212 (Rev.WRC-97)** or a new Resolution.

Another alternative is to modify No. **S5.388** to reflect the revised Resolution **212 (Rev.WRC-97)** in combination with the addition of a footnote **S5.XXX** (see § 1.1.2.5), specifying the additional bands, this footnote having a link to the updated version of Resolution **212 (Rev.WRC-97)** or a new Resolution.

In both alternatives the different dates of availability for the additional IMT-2000 bands could be given in the revised version of Resolution **212 (Rev.WRC-97)** or in the new Resolution.

Advantages

- Having a footnote in the Table of Frequency Allocations for the IMT-2000 additional bands is consistent with the regulatory format adopted at WARC-92 to identify frequency bands for IMT-2000 in No. **S5.388**. The reference to IMT-2000 in the Table of Frequency Allocations highlights the use of these frequencies for IMT-2000 and could therefore facilitate the worldwide implementation of IMT-2000 and global roaming, without preventing administrations to allow other advanced mobile satellite applications in these bands if they wish.
- The harmonization of IMT-2000 spectrum globally is an extremely important issue. There is preference to clearly indicate all IMT-2000 global and regional/subregional frequency bands in a footnote(s) in Article **S5** of the Radio Regulations.

Disadvantage

- This different regulatory format for IMT-2000 systems compared to other mobile-satellite systems or radio services which are not footnoted in the RR, could be misinterpreted as giving a different regulatory status to IMT-2000 compared with other systems.

Method 2

Additional global and regional/subregional bands could be listed in a new WRC Resolution or Recommendation, without any specific identification in a footnote to the RR. Different dates of introduction for additional IMT-2000 bands can be given in this new WRC Resolution or Recommendation. Administrations may implement IMT-2000 systems in any appropriate frequency bands allocated to the MSS, therefore footnotes in Article **S5** are not essential.

One alternative in this method is to maintain unchanged No. **S5.388** and Resolution **212 (Rev.WRC-97)** and to develop a new Resolution listing the additional satellite frequency bands and their dates of availability.

Another alternative would be to suppress both No. **S5.388** and Resolution **212 (Rev.WRC-97)**, and to develop a new Resolution listing both the initial and additional satellite frequency bands for IMT-2000 and their dates of availability.

Advantages

- Avoids misinterpretation of the regulatory status of IMT-2000 by disassociating any additional spectrum identification for IMT-2000 from the Table of Frequency Allocations.
- Similar to Method 1, the reference to IMT-2000 in a WRC Resolution or Recommendation highlights the use of these frequencies for IMT-2000 without preventing administrations to allow other advanced mobile applications in the bands if they wish.

Disadvantages

- Listing the additional IMT-2000 frequency bands in a new WRC Resolution or Recommendation, without a corresponding reference in a footnote in the Table of Frequency Allocations, gives a different regulatory format to the additional bands compared to the WARC-92 bands identified in No. **S5.388**. This might imply a different status between the existing spectrum identified at WARC-92 and the additional IMT-2000 bands. There is also the danger that the Resolution or Recommendation, if not referenced in a footnote, be disregarded by administrations. Furthermore, changing the regulatory format in this way might cause misconceptions that the worldwide implementation of IMT-2000 is becoming a lower priority than originally envisaged. Although it is not unique, some administrations question whether a Resolution, which does not address a transitional measure, is appropriate without any reference in Article **S5**.
- Regardless of which method would be chosen, the following additional provision should be taken into consideration.

Additional provision

Where services other than the MSS operate in frequency band candidates identified in Table 1-4 above, transitional arrangements could be introduced to make these bands fully available for use by the satellite component of IMT-2000.

Advantage

- Facilitates introduction of the satellite component of IMT-2000.

Disadvantage

- Affects other services operating in the bands in question.

1.1.2.5 Regulatory and procedural considerations

Several different methods to satisfy agenda item 1.6.1 are presented in § 1.1.2.4 above.

Some common regulatory provisions are required for all the methods proposed whereas for some of the proposals additional specific regulatory provisions are needed. Additionally, there are a number of possible options available to satisfy the methods indicated:

- Specific regulatory provision will be needed for frequency bands not already allocated to the MSS, in order to allocate them to the MSS on a primary basis. Where bands are allocated to the MSS on a primary basis, consideration needs to be given to the method of identifying these bands for IMT-2000, as indicated in § 1.1.2.4 above.
- It is possible that the additional IMT-2000 bands can be indicated either in a new Conference Resolution or Recommendation or through modification of Resolution **212 (Rev.WRC-97)**. This may lead to the suppression or modification of footnote No. **S5.388**.

For footnotes, if following the format of No. **S5.388**, the required footnotes could be structured as follows:

ADD S5.XXX *(Additional bands for satellite IMT-2000):* The bands [...] are intended for use, by administrations wishing to implement International Mobile Telecommunications-2000 (IMT-2000). Such use does not preclude the use of these bands by other services to which these bands are allocated. The band should be made available for IMT-2000 in accordance with Resolution **212 (Rev.WRC-2000)**/a new Resolution.

As noted in Method 1 in the previous Section, alternative formulations of the footnotes are also possible.

1.1.3 Agenda item 1.6.2

"identification of a global radio control channel to facilitate multimode terminal operation and worldwide roaming of IMT-2000"

1.1.3.1 Conclusions of ITU-R studies

ITU-R has studied the WRC-2000 agenda item 1.6.2 and determined that facilitation of multimode terminal operation and worldwide roaming of IMT-2000 is possible without a specific physical global radio control channel. Accordingly, no recommendation is made for the specific allocation, or identification, of frequencies within the RR at this time.

Further information on the global radio control channel may be found in Document 8-1/226 (Attachment 4, Annex 2, Appendix 1).

****

1.2 Agenda item 1.7

"review of the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to protecting operational, distress and safety communications, taking into account Resolution **346 (WRC-97)**"

*Resolution **346 (WRC-97)** "Protection of distress and safety communications on the frequencies 12 290 kHz and 16 420 kHz from harmful interference caused by these frequencies if also used for non-safety calling"*

1.2.1 Summary of technical and operational studies

HF assignments to Aeronautical (R) users are based on an ITU Allotment Plan set out in Appendix **S27** (see also Article **S41**). Ships and coast stations operate on internationally assigned distress and safety channels, as defined in Article **S52** and Appendices **S13**, **S15** and **S17** of the RR. There are two principle issues which may be addressed under this agenda item.

1.2.1.1 Problem A

The first issue is that the HF band, commonly used on international and domestic routes for communications by aircraft and vessels operating throughout the world, suffers from interference from illegal itinerant sources or use which is in some way in contravention to the RR. Mobile HF

SSB transceivers are often indiscriminately operated by unlicensed users, causing interference to legitimate aeronautical and maritime communications. The interfering signal can be on channel or off tuned. Interference is experienced on all channels from 3 to 16 MHz and occurs daily at different times varying in intensity and duration. Monitoring of these transmissions indicates that the sources are both land- and sea-based. Interference is also experienced from licensed maritime or aeronautical users, but who are operating outside the terms of the RR and are therefore causing interference to legitimate aeronautical and maritime communications. For both types of interfering communications there are cases where it is possible to identify the source of the interference, and cases where it is not possible to identify the source.

Interference to such HF communications is normally reported under Article **S15**. ITU reporting and notification of incidents under Article **S15** has not proved to be effective in the case of this type of interference, which has continued to increase.

1.2.1.2 Problem B

The second issue is that addressed by Resolution **346 (WRC-97)**, that on several maritime HF frequency bands the radiotelephony distress and safety frequencies are also used as international routine calling frequencies. The routine calling causes interference to distress and safety communications.

1.2.2 Analysis of the results of studies

1.2.2.1 Problem A

Administrations in the Asia-Pacific region have been alerted to the problem and are taking action through the Asia Pacific Telecommunity to set up a coordinated monitoring network including direction finding to effectively locate and take action against interfering HF operations. However, in view of the vast areas of sea and land and the multiplicity of islands in the region, elimination of unauthorized operation of HF radios is improbable, since the extensive resources needed for enforcement would not be available.

Action is also being taken by some administrations to curb unlicensed activity by the use of television and radio broadcasts to warn offenders.

Regular reports of severe interference have been submitted to the ITU under Article **S15**. More recently with the increasing involvement of ICAO, interference reports have also been directed to the ICAO regional office in Bangkok.

Further studies are needed to examine possible solutions to this type of interference, in particular that characterized by its emission from unlicensed transmitters which are difficult to locate and control. Technical innovations which would mitigate interference appear to offer the most practical and effective solutions to this type of interference.

In this regard there are several likely techniques that could be adopted. Possibilities include frequency hopping, near vertical incidence sky wave (NVIS), barred frequencies (V-Chip), adaptive arrays, etc.

Recently a technique has been successfully evaluated for mitigating interference on HF communications channels which adopts a programmable HF adaptive receiving system (PHFARS) which selectively cancels interfering signals. PHFARS is being examined as a possible solution to combat interference on civil aviation HF channels.

The ITU-R is studying this issue, including the consideration of interference mitigation techniques and the assessment of their effectiveness in these cases of interference.

Clearly the unpredictable and uncontrollable nature of this type of interference means that any solution to eliminate it should:

- not be costly and complex to implement and should ideally not require modification to aircraft and ship installations;
- not facilitate unauthorized use of the HF band;
- address the need to mitigate interference received by the aircraft/ship stations and by flight service and coast radio stations, and;
- not introduce any risk or threat to aeronautical (R) and maritime communications.

1.2.2.2 Problem B

Resolution **346 (WRC-97)** mentioned in this agenda item is concerned with the protection of HF distress and safety frequencies, in particular the frequencies 12 290 kHz and 16 420 kHz. WRC-97 addressed the problem of interference to distress traffic on these frequencies due to their permitted use as calling frequencies. WRC-97 adopted Resolution **346 (WRC-97)** which called for action from administrations to minimize the use of these frequencies for non-safety calling purposes by coast and ship stations. Since the adoption of Resolution **346 (WRC-97)** no reports have been received indicating that the situation has improved.

The problem seems to be related to the calling ship not being aware of ongoing distress traffic on the ship calling frequency since the ship is tuned to a different receive frequency for coast station calls and replies. The problem is complicated by the transmitting station not adhering to existing regulatory standards which require a station to listen on its transmitting frequency prior to transmitting. This problem occurs in the 4, 6, 12 and 16 MHz bands and not in the 8, 18, 22 and 25 MHz bands.

1.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

ITU-R considers the following methods to be complementary. They may all be implemented by the conference and are not mutually exclusive.

1.2.3.1 Problem A

1.2.3.1.1 Method 1: Time periods for reports on interference

The WRC may consider that Article **S15** is modified to stipulate the time period in which reports of interference are submitted to the administration having jurisdiction over the interfering station or administrations believed to be responsible for the harmful interference. Article **S15** may also state that these administrations should respond in a timely manner.

The Conference may consider modification or adoption of Resolutions (particularly Resolution **207 (Mob-87)**) in order to address issues arising from discussion of this agenda item. These modifications may particularly emphasize that these cases of interference are often caused by unauthorized sources, that there is a need to find solutions to the problem through study, and that ITU and administrations may carry out awareness campaigns.

Advantages

- The quicker a case of interference is reported, the quicker that action may be taken against that interference, and the shorter the duration of the interference should be.

- The inclusion of a particular time period within which cases should be reported would improve the timeliness of reports.
- Modification of Resolution **207 (Mob-87)** would draw the attention of administrations to the fact that this interference is often due to unauthorized sources and to study possible solutions in assisting the mitigation of this interference.

Disadvantages

- This method would not address cases of interference where it is not possible to identify the source.
- It may be difficult to include a time-limit for reporting cases of this type of interference to HF communications, without impacting unfavourably on other obligations of administrations towards wider issues of the ITU and to make such a provision effective.

1.2.3.1.2 Method 2: Modification of Section VI of Article S15

The WRC may consider modification of Section VI of Article **S15**, particularly **S15.28**, to ensure that suitable provision is made for both the aeronautical (R) and maritime services.

Advantage

- Inclusion of suitable provisions in the RR would lead to the protection of frequencies used for the safety and regularity of flight against interference.

Disadvantage

- Modification of Section VI of Article **S15** alone would not solve the problem of HF interference to aeronautical mobile (R) and maritime mobile services from itinerant sources.

1.2.3.1.3 Method 3: Mitigation techniques

The WRC may consider the adoption or continue the study of interference mitigation techniques.

This could be reflected in a modification to Resolution 207 (Mob-87) or through the adoption of a new WRC Resolution.

Advantages

- Mitigation techniques offer the advantage of being effective against both known and unknown cases of interference.
- Adoption of flexible enabling provisions concerning the use of mitigation techniques would allow the development and implementation of such techniques without the need for any further action by a future conference.

Disadvantages

- ITU-R studies on appropriate mitigation techniques have not been concluded.
- In particular, further study of the technical and operational consequences of introduction of mitigation techniques in aircraft operations is required before these techniques could possibly be considered for implementation in the aeronautical HF bands.
- Implementation of mitigation techniques would require a change of equipment, which would place the cost of problem solution on those suffering the interference.

- Adoption of mitigation techniques by victim receivers would not solve the source of the interference.

1.2.3.2 Problem B

Only the first two of the three following proposals is intended to satisfy the agenda item. The third method is presented as a subsequent and supporting action which the conference may consider.

1.2.3.2.1 Method 1: Exclusive HF distress and safety frequencies

The WRC may consider modification of Article **S52** and Appendices **S13** and **S17** in such a way that the HF distress and safety frequencies become exclusive (i.e. that no routine calling on these frequencies is allowed) but that routine voice calling frequencies are also made available.

Advantage

- Vessels which use voice calling for routine calling purposes may continue to do so.

Disadvantage

- Modification of existing equipment may be necessary to allow operation on the new voice calling frequencies selected.

1.2.3.2.2 Method 2: Modification of provisions to enhance compliance

Some administrations felt the WRC may wish to consider minimum modifications required in the Radio Regulations (e.g. Article **S52**) and its Appendices, without the creation of exclusive HF distress and safety frequencies, in order to improve the situation on the HF radiotelephony distress and safety frequencies. However, calling would continue to be permitted on the distress and safety frequencies.

Compliance with existing Radio Regulations, **S52.224,** which requires that stations listen before transmitting, would alleviate this problem.

Advantage

- Further regulations are not required, rather enforcement of the existing regulation is required. Vessels which use distress and safety frequency for routine calling purposes may continue to do so.

Disadvantages

- Due to the construction of ship HF equipment, prior listening on the distress frequency complicates the calling procedure. Experience shows that ship station operators will not often do this.
- Enforcement of the requirement would be difficult, and it would require hardware changes to solve the problem through technical means.

1.2.3.2.3 Method 3: Encouraging the use of Digital Selective Calling

The WRC may further consider methods for encouraging the use of digital selective calling (DSC) instead of calling by radiotelephony.

Advantage

- The use of DSC by all vessels would be promoted, thereby promoting the implementation of the GMDSS.

Disadvantage

- This may cause problems for vessels not fitted with DSC.

1.2.4 Regulatory and procedural considerations

If any of the above Methods are adopted, the appropriate consequential amendments to the RR would need to be considered.

****

1.3 Agenda item 1.18

"to consider the use of new digital technology for the maritime mobile service in the band 156-174 MHz and consequential revision of Appendix **S18**, taking into account Resolution **342 (WRC-97)**"

*Resolution **342 (WRC-97)** "Review of new technology to provide improved efficiency in the use of the band 156-174 MHz by stations in the maritime-mobile service"*

1.3.1 Summary of technical and operational studies

Studies in response to Recommendation **318 (Mob-87)** and Question ITU-R 96-1/8 have been ongoing in ITU-R for a number of years. It has long been recognized that the most likely solution to the problems identified in the present use of Appendix **S18** would be found in the adoption of technologies based on those already implemented in the land mobile service. It is also recognized that the adoption of any new technologies in Appendix **S18** would require a significant period to phase in, and should not disrupt the provision of distress and safety services in the VHF band; see Recommendations ITU-R M.1084 and M.1312.

Changes to the technology used in Appendix **S18** should provide relief of congestion experienced in some parts of the world, and the flexibility to meet the rapidly growing requirement for new services.

The use of the present system operating on the frequencies of Appendix **S18** is changing. In some parts of the world, public correspondence traffic has fallen to uneconomic levels, being replaced in coastal regions by the use of mobile phones. A number of regions find public correspondence channels to be maintaining high levels of traffic due to the implementation of successful local public correspondence systems. At the same time as certain traffic is falling, many administrations are finding that other traffic, particularly port operations, is increasing in congestion.

At a time of great change in global and data communications, maritime operators are keen to take advantage of the opportunities new technologies provide. Many are using systems designed for use in other services for various business and non-safety related purposes. New navigational tools are also taking advantage of digital communications. Some of these communications systems not designed for use in the maritime service are licensed through free circulation, or licence exemption arrangements. However, many such systems are operated without adequate licensing arrangements and not being part of the maritime station, are not covered by the maritime licence.

Some of these newer applications may continue to be best served by these new systems, especially those global systems which have suitable global licensing arrangements. However, many new applications could be provided by the maritime mobile service, providing common international applications, and offering the benefit of improved general communications integrated into the same system as distress and safety communications. Services which could be provided by new technology in the VHF maritime mobile service include data transmission for all purposes such as safety of navigation, business operations, medical situations, and improved public correspondence including Internet and e-mail.

1.3.2 Analysis of the results of studies

WRC-97 made a number of changes to Appendix **S18** to provide administrations with the flexibility to address immediate problems of local congestion. In particular, a footnote was added to Appendix **S18** to allow the use of 12.5 kHz channel interleaving on a non-interference basis to other administrations' and international shipping's use of 25 kHz channels. The conference also identified a number of public correspondence channels as being available for use for port operations and ship movement. This provides administrations which have a decrease in the use of public correspondence services with the opportunity to use under-utilized channels for the services where congestion is still experienced.

Resolution **342 (WRC-97)** was adopted by the Conference and details the studies necessary to progress within ITU-R the development of new technologies for use in the channels of Appendix **S18**. However, ITU-R has not completed these studies as detailed in Question ITU-R 96/8 and Resolution **342 (WRC-97)**. It is clear from the status of studies in the ITU-R that any revision of the present Appendix **S18** to introduce new technologies should be considered only for non-operational purposes at this·Conference.

1.3.3 Methods to satisfy the agenda item and their advantages and disadvantages

The modification of Appendix **S18** allowed for by this agenda item has been identified by ITU-R as intending to fulfil two roles: providing the possibility to implement new applications; and the relief of congestion experienced in certain parts of the world. Whilst the status of the ITU-R studies indicate that it may be difficult for the conference to carry out the revision of Appendix **S18** in order to introduce new digital technologies, it may be possible for the conference to take action to address the issue of congestion.

1.3.3.1 Modifications to Appendix S18

The Conference could consider modifications to Appendix **S18** which would provide administrations with further flexibility to use some of the channels of Appendix **S18** in simplex mode if required. Furthermore, the conference could consider permitting, subject to non-interference and no protection, the use of some of these channels or sub-bands created by the conversion of duplex channel to simplex channels for the initial testing and possible future introduction of new technologies, subject to non-operational use. This would necessarily be subject to special arrangement between interested or affected administrations.

Advantages

- Allowing the use of duplex channels in Appendix **S18** in simplex mode would increase the number of available channels.
- The cost of the change to the user, not taking into account new technology would be minimal, requiring at most a change to equipment software.
- Administrations would be able to quickly address certain local problems of congestion.

- The necessary change would be straightforward for the conference to make, basing the change on actions taken at the last conference.
- May permit facilitation of the development and testing of new technology.
- Use of channels for the development and testing of new technologies may, in turn, encourage maritime radio equipment manufacturers to advance or accelerate such development and testing.

Disadvantages

- This would only provide a limited and short-term improvement to congestion problems.
- Administrations implementing all the available channels in simplex mode would have no more duplex channels available.
- The need for coordination between administrations would increase.
- There may be a problem of equipment meeting international standards and operating worldwide.
- Use of channels for the development and testing of new technology may appear to prejudge the outcome of requested studies by the ITU-R.
- Use of channels for testing may increase the channel loading of the remaining operational channels for the concerned administrations.

1.3.4 Regulatory and procedural considerations

If the above Method is adopted the appropriate consequential amendments to the RR would need to be considered.

CHAPTER 2

Mobile-satellite and radionavigation-satellite services

(WRC-2000 agenda item 1.10)

CONTENTS

Mobile-satellite and radionavigation-satellite services

Introduction - Spectrum requirements

Part A - MSS spectrum requirements in the 1 to 3 GHz range (agenda items 1.9, 1.10)

The need for additional spectrum for the MSS in the 1 to 3 GHz range has been stated in the CPM Reports to the last two WRCs. The CPM to WRC-95 indicated that a total allocation of between 2 x 75 MHz and 2 x 150 MHz would be required by 2005 (Chapter 2, part A.2, § 3). Two years later, the CPM to WRC-97 indicated that 2 x 250 MHz would be necessary by 2010 (Chapter 4, § 4.2.6).

Two recent submissions to ITU-R, one a compendium of studies, based on conservative assumptions of MSS traffic growth and realistic MSS spectrum efficiency, have forecast a minimum MSS spectrum demand of between 2 x 125 MHz and 2 x 145 MHz by 2010, depending on the geographic region. (See also § 2.1, which in the context of Resolution **218 (WRC-97)** addresses AMS(R)S spectrum requirements that are a subset of the overall MSS spectrum requirements.) These studies are consistent with the spectrum demand estimates presented in Report ITU-R [IMT.SPEC], which are detailed in § 1.1 (part B.2) in the context of the satellite component of IMT-2000. It is important to note that although it is foreseen that some or all of the spectrum requirements for the satellite component of IMT-2000 may be accommodated in the existing MSS allocations, as discussed in § 1.1.2, additional MSS allocations are needed to meet the projected total MSS spectrum requirements, since the satellite component of IMT-2000 is only a subset of the MSS. Indeed, identification of the existing MSS allocations for the satellite component of IMT-2000 places additional emphasis on the need for additional allocations to support both IMT-2000 and non-IMT-2000 MSS requirements.

Since all studies indicate that there is a requirement for additional MSS spectrum in 1-3 GHz to meet the demand of MSS in time, including the satellite component of IMT-2000, all existing worldwide MSS allocations should be retained for MSS use.

Currently the Radio Regulations allocate about 2 x 115 MHz to the MSS in 1-3 GHz, with some variations among the ITU Regions. It should however be noted that most of these bands are used by other services in most countries, significantly reducing the actual availability of those bands for the MSS, and in many countries they are not available for MSS at all. This applies in particular to the bands 1 980-2 010/2 170-2 200 MHz (and 2 010-2 025/2 160-2 170 MHz in Region 2), 2 500-2 520/2 670-2 690 MHz and 2 520-2 535/2 655-2 670 MHz (MSS use of this band is subject to agreement obtained under No. **S9.21** and for operation within national boundaries), which are heavily used mainly by terrestrial fixed services in many countries. In order to satisfy the MSS spectrum requirements it is essential to facilitate the MSS access to spectrum already allocated to the MSS, taking into account other services with a co-primary allocation.

The bands 1 525-1 559/1 626.5-1 660.5 MHz and 1 610-1 626.5/2 483.5-2 500 MHz are rapidly approaching saturation due to an increasing number of operational and planned MSS systems with growing spectrum requirements. This has become apparent in the annual multilateral coordination meetings in all Regions with respect to the first pair of bands. As other MSS bands in 1-3 GHz become available, these bands will also rapidly reach saturation when the satellite networks are brought into operation.

The need for additional MSS spectrum was highlighted in Resolution **213 (Rev.WRC-95)**. Considering the results of studies reported in § 2.2.1, if a suitable MSS downlink allocation cannot be found through the studies completed under Resolution **220 (WRC-97)**, every effort should be made to find a suitable MSS downlink allocation, taking into account the results of already available ITU-R relevant sharing studies.

Solutions need to be sought urgently to accommodate the MSS spectrum demand in the 1-3 GHz range (i.e. the technically preferred range), while taking due account of the needs of other services. Such solutions may include making available the existing MSS allocations in a timely manner and making limited additional MSS allocations that are not constrained by shared services. If there are still requirements that remain unsatisfied after WRC-2000, it may be necessary to consider the issue of MSS spectrum requirements in the 1-3 GHz range at future WRCs.

Part B - MSS spectrum requirements below 1 GHz (agenda item 1.11)

A total of 1.525 MHz (space-to-Earth) and 1.9 MHz (Earth-to-space) are presently allocated on a worldwide primary basis to the MSS below 1 GHz and 300 kHz (Earth-to-space) is allocated for land MSS on a worldwide primary basis. An additional 151.5 MHz may be used subject to agreement obtained under provision No. **S9.21**. It is difficult to implement MSS systems in this 151.5 MHz of spectrum subject to No. **S9.21** because of the need to obtain agreements with many countries. In addition, 2 MHz (Earth-to-space) in Region 2 is allocated to the MSS below 1 GHz. Some individual countries have additional allocations (Earth-to-space) for the MSS below 1 GHz, appearing in footnotes. These allocations are for both the MSS service links and feeder links.

The Radiocommunication Bureau has identified 25 non-GSO MSS networks as of 26 November 1999, at frequencies below 1 GHz, at some state of coordination under No. **S9.11A**/Resolution **46 (Rev.WRC-97)**, and nine non-GSO MSS networks at the advance publication stage only. However, it appears that many of the proposed networks cannot be implemented in the existing allocations because there is not enough spectrum readily available without applying **S9.21** to allow the development of all of these systems.

It had previously been identified in the CPM Report for WRC-95 and is also stated in *considering b)* of Resolution **214 (Rev.WRC-97)** that 7 to 10 MHz of additional spectrum is required for MSS below 1 GHz. An extensive study carried out by an administration in 1996 identified a need for spectrum beyond the current allocations to provide for certain applications until the year 2002. This study identified a spectrum requirement for service links of about 17 MHz on a shared basis, and an additional 4 MHz of shared spectrum for feeder links. In arriving at the conclusions regarding spectrum requirements and market demand, the study took into account the ability of present and future competing terrestrial and satellite technologies to provide these applications. This study estimated that when the data rates and frequency of use among the various users are taken into account on a worldwide basis an average of 3.2 million non-GSO MSS users would be provided service in each 1 MHz of bandwidth for uplinks, and 6.1 million users per MHz for downlinks.

Since the 1996 market study referred to above, there have been more recent reports carried out in 1997-1998. These reports describe the estimated market for non-GSO MSS services and support the estimates made in the original 1996 market study.

In general, the uplink and downlink allocations should be approximately balanced for CDMA systems. A wider uplink allocation, however, facilitates co-frequency sharing with other services; the wideband MSS system can operate with a lower power density by spreading over wider bandwidths. Narrow-band FDMA systems with dynamic channel selection will occupy any given sub-channel less often and will require a greater bandwidth to achieve a given message rate. Thus, the uplink and downlink allocations do not necessarily have to be equal.

The frequency range 470-862 MHz is not considered in this Chapter because studies relating to consideration of allocations in this range to non-GSO MSS are carried out by ITU-R according to Resolution **728 (WRC-97)** which is not a part of WRC-2000 agenda.

Part C - RNSS spectrum requirements (agenda item 1.15)

RNSS spectrum is being used to the fullest capacity in support of a large and expanding base of users worldwide. There are over eight million Radionavigation-Satellite Service (RNSS) receivers in use today for a wide range of applications, including safety-of-life, critical navigation on land, at sea, and in the air. As discussed in § 2.2, the current RNSS allocations, of 1 559-1 610 MHz and 1 215-1 260 MHz, are of great importance to the Global Navigation Satellite System (GNSS) which today consists of the United States Global Positioning System (GPS), the Russian Federation Global Navigation Satellite System (GLONASS), space and ground-based augmentation systems, and pseudo-satellites (pseudolites). New generations of GPS and GLONASS satellites are being designed. Plans are currently under consideration that could alter the Y-code and Coarse/Acquisition (C/A) code assignments for future GPS in the bands 1 559-1 610 MHz and 1 215-1 260 MHz.

In addition to the current RNSS systems operating in the 1 559-1 610 MHz and 1 215-1 260 MHz bands three systems have been advanced published by ITU-R, LSATNAV and MSATNAV proposed by the CNES French Space Agency and E-NSS-1 proposed by the European Space Agency. The European Union has also announced preliminary plans for the implementation of a European RNSS system, Galileo, which will also operate in the 1 559-1 610 MHz and 1 215-1 260 MHz bands. It is clear that the current RNSS allocations are extensively used, and will continue to undergo an extremely rapid expansion that will drive further evolution. As a result, all existing worldwide RNSS allocations should be retained for RNSS use.

There is a requirement for additional RNSS spectrum in the bands between 1 and 6 GHz to support worldwide satellite navigation developments in both the space-to-Earth and Earth-to-space directions of transmission. For example, the United States has announced that it intends to provide an additional GPS signal in the space-to-Earth direction for civil users. The European Union is also exploring the desirability of using new RNSS bands for Galileo. This matter will be discussed under agenda item 1.15.1 of WRC-2000 and is treated fully in § 2.4.1 of this Chapter. These additional allocations will enable GNSS operations with greatly improved performance characteristics (accuracy, availability and continuity). GNSS operations in widely spaced multiple frequency bands is necessary to support improved ionosphere corrections and phase tracking capabilities, which are essential for robust and precise navigation. An RNSS system using higher code rates to give better navigation accuracy and reduce multipath errors is required to satisfy the navigation requirements of tomorrow. An additional 20 to 24 MHz of spectrum is needed for such a wideband signal. The spectrum that is allocated to RNSS is occupied by existing (GPS and GLONASS) and planned systems (LSATNAV, MSATNAV, E-NSS-1) to such an extent that the required bandwidth for additional RNSS signals is not available. The bands under consideration for a new RNSS allocation include: parts of 1 151-1 215 MHz, 1 260-1 300 MHz and parts of 5 010-5 150 MHz in the space-to-Earth direction and 1 300-1 350 MHz and 5 000-5 030 MHz in the Earth-to-space direction.

****

2.1 Agenda item 1.10

"to consider results of ITU-R studies in accordance with Resolution **218 (WRC-97)** and take appropriate action on this subject"

*Resolution **218 (WRC-97)** "Use of the bands 1 525-1 559 MHz and 1 626.5-1 660.5 MHz by the mobile-satellite service"*

2.1.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations and provisions of the RR

Relevant provisions: No. **S5.353A** and No. **S5.357A**

Relevant ITU-R Recommendations: M.1089, M.1180, M.1229, M.1233 and M.1234.

2.1.2 Analysis of the results of studies

In the context of Resolution **218 (WRC-97)**, "prioritization" means assignment by the network of the first available channel to the traffic within the AMS(R)S priority 1-6 in Article **S44** or distress, urgency and safety communications of the GMDSS in accordance with No. **S5.353A.** "Pre-emption", means termination of some non-safety communications by the network to establish the distress, urgency or safety communications

Within a network, under the definitions given above, prioritization and real-time pre-emption are deemed to be feasible and have been implemented in the AMS(R)S. However, an existing system has found that for its system, the complexity and cost of implementing intra-system prioritization and pre-emption between different types of MES standard designations is substantially greater than within one standard designation. Further studies are required to define the technical and operational requirements that will satisfy the needs of the AMS(R)S/GMDSS. Further studies are also required with respect to the implementation of a system that could use spectrum flexibly between different MSS networks.

Possible impact on future spectrum requirements could result from the addition of redundant satellite system capability for the provision of AMS(R)S as well as the initiation of new types of data service.

2.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

2.1.3.1 Accommodation of distress, urgency and safety traffic in the GMDSS and AMS(R)S communications with priority 1-6 of Article S44

The following methods can be considered as means of providing access to spectrum for distress, urgency and safety communications of the GMDSS and AMS(R)S as referred to in Resolution **218 (WRC-97)**. Whenever the terms "distress, urgency and safety communications" are used in reference to the bands 1 530-1 544 MHz/1 626.5-1 645.5 MHz and 1 545-1 555 MHz/ 1 646.5-1 656.5 MHz they refer to communications in accordance with Nos. **S5.353A** and **S5.357A**.

2.1.3.1.1 Intra-system, inter-service prioritization and pre-emption

The need for resorting to intra-system pre-emption of an MSS call will arise when all the spectrum, which that system has coordinated within the spectrum in which Nos. **S5.353A** and **S5.357A** apply, is at that instant being fully used and additional distress, urgency or safety traffic needs to be accommodated. In such a situation, one way to accommodate the additional traffic could be to build-in prioritization and pre-emption for distress, urgency or safety traffic over other MSS traffic as necessary, in any part of the relevant MSS bands quoted in the footnotes to which access has been coordinated for that system.

The following technical provisions would be required to implement intra-system prioritization and pre-emption and are applicable in the bands covered by the footnotes providing priority for GMDSS and AMS(R)S:

i) MSS space, feeder link and control elements are to be capable, by design, of supporting the transmission of messages compliant with ICAO SARPs and/or GMDSS;

ii) user terminals in the satellite networks providing AMS(R)S and/or GMDSS need to be placed under a control system which is capable of supporting AMS(R)S and/or GMDSS priority and real-time pre-emption;

iii) user terminals in the satellite network providing AMS(R)S services need to be designed and operated in conformance with Recommendation ITU-R M.1234;

iv) MSS space, feeder link and control elements need to be designed such that the AMS(R)S or GMDSS services could be integrated into the system operation. Specific design requirements must be clearly identified to ensure acceptable integration of the AMS(R)S and/or GMDSS.

In addition, this scenario would require that the operation of any MES that accesses the relevant bands in an MSS system, providing AMS(R)S and GMDSS, be subject to certain requirements. These include:

i) the terminals need to be frequency agile;

ii) the terminals need to be automatically tuneable to any forward and return channel pair;

iii) transmit and receive function need to be under constant control;

iv) control protocols need to be implemented to permit pre-emption in a timely manner (to be identified by further study);

v) the terminals must be assigned a communications channel before transmission is initiated.

Under this scenario the requirements of distress, urgency or/and safety traffic of AMS(R)S and GMDSS could be met by that system until the entire spectrum coordinated by that system in the relevant bands is full of such calls.

2.1.3.1.2 Inter-system prioritization and pre-emption

Under an alternative scenario there may be multiple MSS service providers, some of which provide for AMS(R)S and GMDSS. In this situation there could be yet another way of accommodating additional distress, urgency or safety traffic. This possibility will arise when system A's coordinated spectrum within the spectrum in which Nos. **S5.357A** and **S5.353A** apply is full of such traffic while system B's coordinated spectrum within the same bands is not fully used by the applicable traffic. System A's distress, urgency or safety traffic would then be accommodated by the spectrum transferred by system B to system A on a temporary basis to alleviate the congestion. System B would initially transfer spectrum not currently in use and use pre-emption of ongoing calls as a last resort. There are MSS systems in operation today that are capable of transferring spectrum not actively used by their system and pre-empting ongoing calls. What remainss in question are the overall feasibility of this option and the definition of the mechanisms for transferring such spectrum temporarily to another system.

2.1.3.1.3 Capacity planning

Under this approach the system operators, which provide AMS(R)S/GMDSS, with the guidance and support of their administrations, coordinate from time to time with other operators using the spectrum to which Nos. **S5.353A** and **S5.357A** apply, access to the amount of spectrum needed to accommodate the requirements of AMS(R)S/GMDSS. This option would accommodate the distress, urgency or safety traffic of AMS(R)S/GMDSS and can be categorized as capacity planning. This process should be able to ensure that the required amount of spectrum would always be available for such usage until such time as distress, urgency and safety requirements reach the spectrum allocated under Nos. **S5.353A** and **S5.357A** for the GMDSS and AMS(R)S respectively. This procedure is in fact used today through the multilateral frequency coordination process.

2.1.3.1.4 Discussion of options

The choice of the option for implementation will depend upon the spectrum requirements and the relative advantages and disadvantages of each of the options outlined above, which requires further evaluation. The current state of growth of AMS(R)S suggests that the capacity planning option given in § 2.1.3.1.3 may satisfy the AMS(R)S/GMDSS requirements in the short to medium time-frame.

Although the option in § 2.1.3.1.1 is deemed to be feasible, due to the need for implementation of the features listed in § 2.1.3.1.1, this option is expected to entail additional cost and operational complexities in network control systems and network operations, in comparison to systems without full pre-emption capabilities. Further studies on options in § 2.1.3.1.1 are needed. It should also be noted that study of option § 2.1.3.1.2 is needed.

In the longer term, and as the future scenario becomes clearer, § 2.1.3.1.1 and/or § 2.1.3.1.2 may be considered. This longer-term consideration should focus more generally on future systems in order to minimize the impact on current users.

Studies on establishing the feasibility of and defining a mechanism for facilitating inter-system prioritization and pre-emption should be expedited. The studies need to be conducted within ITU-R with the participation of ICAO, IMO, interested administrations and MSS operators.

2.1.3.2 Spectrum requirements for the provision of GMDSS and AMS(R)S communications

Two studies have been performed that used significantly different assumptions to calculate the future spectrum requirements of AMS(R)S. A study prepared by ICAO and IATA, based on the ICAO CNS/ATM system, which is presently being implemented, established that the future spectrum requirements of AMS(R)S will be 10.8 MHz by 2010. Additional spectrum, which may be required beyond 2010 is under study. A second study prepared by one administration indicated that the future spectrum needs of AMS(R)S could be accommodated in 1 MHz of spectrum by 2025. Significant disagreement exists on the approaches and methodologies to be used in such studies.

Introduction of AMS(R)S traffic in MSS systems which are not operating in the bands 1 525-1 559 MHz and 1 626.5-1 660.5 MHz may affect the spectrum requirements for AMS(R)S traffic in these bands. Introduction of MSS systems in the 1 525-1 559 MHz and 1 626.5-1 660.5 MHz bands that do not intend to provide AMS(R)S may also affect spectrum availability.

The spectrum requirements of distress, urgency and safety communications of the GMDSS and AMS(R)S can be met in the future by giving priority to the accommodation of the spectrum requirements for these types of communications within the spectrum in bands where Nos. **S5.357A** and **S5.353A** apply. Setting aside dedicated spectrum segments for distress, urgency and safety communications would have the disadvantage that the amount of exclusive spectrum would have to correspond to the amount needed to cope with the worst possible case spectrum usage, which could result, from time to time, due to the combination of such conditions as, for example, airport closures, severe storms and maritime and aeronautical emergencies. As this amount would be many times greater than the average use, this would lead to inefficient use of the spectrum, since the allocated spectrum will only be used on rare occasions.

2.1.4 Regulatory and procedural considerations

Administrations are required to accommodate AMS(R)S and GMDSS communications in bands where Nos. **S5.357A** and **S5.353A** apply. The Conference may wish to request, as a matter of urgency, further technical and regulatory studies by ITU-R by means of a suitable resolution. Regulatory provisions may need to be modified or added to by WRC-2000 to ensure that future spectrum requirements are met for the AMS(R)S in the bands where No. **S5.357A** applies and the GMDSS in bands where No. **S5.353A** applies.

****

2.2 Agenda item 1.9

"take into account the results of ITU-R studies in evaluating the feasibility of an allocation in the space-to-Earth direction to the mobile-satellite service in a portion of the 1 559-1 567 MHz frequency range, in response to Resolutions **213*(Rev. WRC-95)*** and **220 (WRC-97)**"

*Resolution **213(Rev. WRC-95)** "Sharing studies concerning possible use of the band 1 675-1 710 MHz by the mobile-satellite service"*

*Resolution **220 (WRC-97)** "Studies to consider the feasibility of using a portion of the band 1 559-1 610 MHz by the mobile-satellite service (space-to-Earth)"*

2.2.1 Band 1 559-1 567 MHz

2.2.1.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

The frequency range under consideration, 1 559-1 567 MHz, is allocated on a co-primary basis to RNSS (space-to-Earth) and ARNS. Additionally, the band is allocated to the FS in some countries. Work has been carried out by various administrations leading to the following Recommendations: ITU-R M.1088, M.1317, M.1318, M.1343, and ITU-R M.[RNSS.CHAR].

Studies have been carried out by ITU-R in response to Resolution **220 (WRC-97)**. Among the studies conducted is an assessment of the impact of pseudo-satellites (pseudolites) (for details see § 2.2.1.2.3) operating in the aeronautical radionavigation service (ARNS) in the band 1 559-1 567 MHz on the feasibility of sharing between MSS and ARNS/RNSS. Other studies have examined whether the proposed power flux-density of -112 dB(W/m^2·MHz) would provide protection to existing and planned RNSS systems.

2.2.1.2 Analysis of the results of studies

2.2.1.2.1 Current uses of the RNSS in the 1 559-1 610 MHz band by GNSS receivers

There are millions of RNSS receivers in use today for a wide range of applications, including safety-of-life, critical navigation on land, at sea, and in the air (see Table 2-1). Today, many of these receivers operate with the Global Positioning Satellite (GPS) system, an element of the Global Navigation Satellite System (GNSS) whose first-generation operates in the 1 563.42-1 587.42 MHz portion of the 1 559-1 610 MHz ARNS/RNSS band.

TABLE 2-1

Examples of uses of RNSS

AGRICULTURE and FORESTRY Forest area and timber estimates. Identifying species habitats. Fire perimeters. Water resources. Locating property boundaries. Ploughing, planting and fertilizing without operators.	**MARITIME and WATERWAYS** Navigation on the high seas. Search and rescue. All weather harbour approach navigation. Vessel traffic services. Dredging of harbours and waterways. Positioning of buoys and marine navigation aids. Navigation for recreational vessels. Location of commercial fishing traps and gear. Offshore drilling research. Monitoring deflections in dams as a result of hydrostatic and thermal stress changes. Ice breaking and monitoring icebergs and flows. Observing tides and currents. Harbour facility management. Location of containers in marine terminals.
AVIATION Oceanic and en route navigation. Non-precision and precision all-weather approaches. Direct routing of aircraft for fuel savings. Improved aircraft separation standards for more efficient air traffic management. Airport surface traffic management. Monitor wing deflections in flight. Wind shear detection. Precise airfield and landing aid locations. Seamless (global) air space management. Less expensive avionics equipment. Monitoring aircraft locations in flight. Precision departures. Missed approach applications Enhanced ground proximity warning system. Automatic dependent surveillance.	**PUBLIC TRANSPORTATION** Bus fleet on-the-road management. Passenger and operator security monitoring. **RAILROAD** Railroad fleet monitoring. Train control and collision avoidance. Facility inventory control and management.
ELECTRIC POWER Synchronization of power levels. Event location. **EMERGENCY RESPONSE** Ambulance, police, and fire department dispatch. Road service locating disabled vehicles.	**RECREATION** Hiking and mountain climbing. Measuring at sports events. Setting lines on sports fields.
ENVIRONMENTAL PROTECTION Hazardous waste site investigation. Ground mapping of ecosystems. Oil spill tracking and cleanup. Precise location of stored hazardous materials.	**SURVEYING** Electronic bench marker providing absolute reference of latitude, longitude and altitude. High precision surveys in minutes by anyone. Real-time dam deformation monitoring. Hydrographic surveying. Efficient and accurate photo surveys. Measuring areas without triangulation. Oil and mineral prospecting. National spatial data infrastructure.
HIGHWAY and CONSTRUCTION Intelligent vehicle-highway system operation. Highway facility inventory and maintenance. Accident location studies. Highway construction. Navigation for motor vehicle drivers. Truck fleet on-the-road management. Monitoring status of bridges.	**TELECOMMUNICATIONS** Precise timing for interlacing messages/network synchronization. **WEATHER, SCIENTIFIC and SPACE** Use as weather balloon position radiosonde. Measurement of sea level from satellites.
LAW ENFORCEMENT and LEGAL SERVICES Tracking and recovering stolen vehicles. Tracking narcotics and contraband movements. Maintaining security of high government officials and dignitaries while travelling. Border surveillance. Measuring and recording property boundaries. Tort claim evidence in aviation and maritime accidents.	Navigating and controlling space shuttles. Placing satellites into orbit. Monitoring earthquakes and tectonic plates. Measuring ground subsidence (sinking). Measuring atmospheric humidity from ground. Precise global mapping of ionosphere.

GLONASS and GPS are established elements of the International Civil Aviation Organization (ICAO) GNSS, operating in the band 1 559-1 610 MHz. These systems are accepted by the ICAO Council for use in international civil aviation. ICAO is currently developing Standards and Recommended Practices (SARPs) for international application in civil aviation. Some of the receiver characteristics used in these SARPs differ from those in Recommendations ITU-R M.1088 and M.1317 (see draft new Recommendation ITU-R M.[RNSS.CHAR]). The GNSS will be used during all phases of flight, including precision approaches and landing, and under all weather conditions. The latter places extensive requirements on the performance characteristics of the system. The aeronautical use of RNSS is recognized in the RR as a safety-of-life application.

The lower portion of the band 1 559-1 610 MHz, where GPS operates, is of great importance to GNSS. GPS provides position and time information to users by means of one-way transmissions using RNSS (space-to-Earth) allocations. GPS is information technology that uses systems of hardware and software, as well as information (time and ephemeris) transmitted from satellites to provide derived information to the user. Conventional GPS receivers in commercial use receive and decode the 1.023 Mbit/s code. Many receivers, used for precise navigation, timing and positioning, in surveying, agriculture, hydrology and other applications, also receive and process, but do not decode, the 10.23 Mbit/s codes on the 1 575.42 MHz and 1 227.6 MHz carriers. These latter receivers, which include safety-of-life applications, may be more sensitive than conventional receivers to interference from sources such as commercial MSS satellite transmitters.

GPS and GLONASS are the sole bases for the formation of International Atomic Time (TAI) and Coordinated Universal Time (UTC) by the International Bureau of Weights and Measures (BIPM). These systems are also the primary means by which clocks are synchronized within telecommunications networks for Time Division Multiple Access (TDMA) transmissions. Time and frequency functions are or will be available on other RNSS systems.

2.2.1.2.2 Considerations for the future use of the RNSS allocation at 1 559-1 610 MHz

As Resolution **220 (WRC-97)** recognizes, RNSS and ARNS systems are evolutionary, and other types of GNSS are under development for operation in the band 1 559-1 610 MHz. There are both aeronautical and non-aeronautical safety-of-life services in the 1 559-1 610 MHz band, and it is well-established (see No. **S4.10**) that there is an essential need to protect systems operating in the ARNS and RNSS. GPS and GLONASS space-based augmentation systems and associated ground-monitoring receivers plan to utilize signals with high associated chipping rates.

New generations of GPS and GLONASS satellites are being designed. Plans are currently under consideration that could alter the Y-code and C/A code assignments for future GPS in the bands 1 559-1 610 MHz and 1 215-1 260 MHz, and to add one or more signals using frequencies offset from those existing signals, to enhance civil applications while maintaining backward compatibility. In addition, other administrations have notified the ITU of proposed new RNSS systems (e.g., E-NSS-1, LSATNAV, and MSATNAV) that would operate in the 1 559-1 610 MHz band. It is anticipated that there will be additional break-through in the use of satellite-based GNSS signals that cannot be properly modelled today.

2.2.1.2.3 Use of the ARNS allocation by pseudolites

Use of the band 1 559-1 567 MHz by pseudo-satellites (pseudolites) in the ARNS/RNSS band at 1 559-1 610 MHz is presently undergoing field trials. Commercial deployment is under way in several countries in the band 1 559-1 610 MHz, and more widespread deployment is planned. Worldwide deployment of pseudolites for aviation is under consideration, with the band 1 559-1 610 MHz as a prime candidate. Pseudolites are ground-based radio transmitters that transmit signals that are similar to and fully compatible with those that come from RNSS satellites, and with some using high chipping rates and frequencies offset from 1 575.42 MHz, in the band 1 559-1 567 MHz. As an augmentation to the performance of RNSS systems, pseudolites provide additional ranging signals and are intended for use in safety-critical applications where a minimum level of positioning performance must be guaranteed.

Through the use of pseudolites to increase the availability of positioning information, the occurrence of service outages has been reduced. Pseudolites are especially valuable when the application involves a safety critical service requiring high availability and reliability, or when users are near obstructions. Field trials, using split spectrum GPS C/A code modulation, conducted at an open pit mine, confirmed this commercial utility. Pseudolites will be particularly useful for helicopters, which often operate in rural and urban environments where terrain or man-made obstructions impact the visibility of satellites from which positioning information is sought. The trials also showed that pseudolites have utility for safety-critical applications in such non-aviation settings as precision construction and mining. The use of pseudolites is expected to proliferate around airports, and to extend to harbours, navigable waterways, and other urban, rural, and topographically challenging environments.

It is anticipated that these pseudolites will further evolve beyond those that exist today. The use of split spectrum pseudolites is currently under investigation.

2.2.1.2.4 Possible uses by the MSS of the band 1 559-1 567 MHz

It is noted that GNSS operations in the 1 559-1 610 MHz band are subject to very stringent requirements with respect, *inter alia*, to integrity and continuity of the services in order to ensure flight safety. All elements of GNSS operations in these bands - including the national RNSS satellite systems, space-based augmentation systems, and emerging ground-based augmentation systems that employ ARNS pseudolites - are designed to be interoperable. In addition each includes a system of monitors to ensure the integrity of aviation navigation and redundant sources of ranging signals to ensure the continuity of flight operations.

The discussions of potential MSS (space-to-Earth) sharing of the 1 559-1 567 MHz band contain no demonstration of how such an MSS system would accomplish fault detection and reporting or data archiving, and the impact of MSS (space-to-Earth) signals on continuity failures has not been assessed. No finding of sharing feasibility between the MSS (space-to-Earth) and ARNS/RNSS can be made without a complete and acceptable demonstration of how such signals would be monitored, how aircraft would be notified of ensuing anomalies, and the manner in which MSS signal parameters would be archived. For example, any unexpected increase in the aggregate power flux-density will be of concern. Such an unexpected increase may be due to a fault in the power control for a single satellite or it could be due to simultaneous transmission from an unexpected multiplicity of satellites. As another example, spectral concentration of MSS power may be of concern, because GNSS performance can be much more sensitive to narrow-band interference than wideband. In addition, no finding of feasibility of sharing can be made until the impact of MSS on the failure rates required for the continuity of flight operations is both understood and negated.

2.2.1.2.5 Analysis of data and results of sharing studies

The core signal structures of MSS and RNSS/ARNS are fundamentally different: MSS uses a two-way signal while ARNS/RNSS transmits a weak, receive-only signal. Having systems from a radiocommunication service operate on a co-primary basis in the 1 559-1 610 MHz band would limit ARNS/RNSS operators' flexibility by reducing the spectrum available for use in the band, and could therefore hamper the development of a GNSS that meets evolving international needs and provides adequate protection for international civil use worldwide.

Resolution **220 (WRC-97)** recognizes the essential need to protect ARNS/RNSS systems operating in the 1 559-1 610 MHz band. The unique technical characteristics of GNSS, and its safety-of-life applications, makes it extremely difficult to predict the operational consequences of such signal sharing.

It should be stressed, however, that sharing studies, while having considered a representative cross-section of RNSS receivers, have not considered the full range of receivers for GNSS applications (see Table 2-1).

a) Impact of pseudolites on potential MSS (space-to-Earth) operations in the band 1 559-1 567 MHz

Ground-based pseudolites are compatible with RNSS space-based transmissions in the same frequency band only because the ground-based transmission has been crafted to take advantage of the specifics of the space-based signal structure-driven user equipment. As noted above, the use of pseudolites is expected to proliferate, although the exact frequencies of operation may vary from country to country.

Studies in the ITU-R have shown that pseudolite deployment would significantly interfere with MSS (space-to-Earth) in the band 1 559-1 567 MHz when there is insufficient geographic separation. As a result, the ITU-R has concluded that with the expected widespread deployment of pseudolites, it is unlikely that there will be opportunities for sharing between MSS (space-to-Earth) and pseudolites in this band.

b) Impact of interference to ARNS/RNSS from potential MSS (space-to-Earth) operations in the band 1 559-1 567 MHz

The ITU-R has examined the claims of some administrations (reported in Resolution **220 (WRC-97)** at *considering d)*, to the effect that an aggregate power flux-density limit at the Earth's surface of -112 dB(W/(m^2·MHz)) in the entire band 1 559-1 567 MHz for all angles of arrival from the MSS space station would protect the ARNS and RNSS services. Studies evaluating the impact on several existing and planned RNSS systems of such MSS (space-to-Earth) systems in the 1 559-1 567 MHz band have since been completed.

One such study, reporting results on the significance of the interference to be caused to existing GPS, shows that sharing is not feasible due to a slight exceedance of the required interference criteria. Another study shows that the interference impact on existing GPS is negligible based on the fact that the previously mentioned study relies on an frequency dependent rejection factor averaged over the 1 559-1 567 MHz band that is at least 10 dB lower than the theoretical value. The ITU-R was unable to explain this discrepancy between the experimental and theoretical results.

All studies agree, however, that, at the very least, such MSS systems would preclude the introduction of new RNSS applications in the band 1 559-1 567 MHz and might preclude the evolution of GPS by preventing the use of the lower part of the existing GPS frequency assignment.

It is therefore concluded that sharing between ARNS/RNSS and MSS (space-to-Earth) is not feasible in any portion of the 1 559-1 567 MHz band.

2.2.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

Studies conducted in the ITU-R indicate the incompatibility of the MSS (space-to-Earth) and ARNS/RNSS in any portion of the 1 559-1 567 MHz band. Not only do MSS signals have the potential to cause significant interference to ARNS/RNSS, but GNSS pseudolites and proposed new RNSS systems also have the potential to cause significant interference to the MSS (space-to-Earth).

The RNSS is extensively used, and is continuing to undergo a tremendous expansion that drives further evolution. As a result of these factors, which have to be considered in conjunction with the many critical timing, positioning, and navigation uses of RNSS (including, but not limited to, aeronautical and maritime safety-of-life navigation), sharing of the 1 559-1 610 MHz band - including any portion of the segment at 1 559-1 567 MHz - with any co-frequency communication service is not recommended.

Although studies were not carried out on every different type of RNSS receiver used in all the numerous applications of RNSS, it was nevertheless possible to conclude that sharing between ARNS/RNSS and MSS (space-to-Earth) is not feasible in any portion of the 1 559-1 567 MHz band.

2.2.1.4 Regulatory and procedural considerations

No practically implementable regulatory or procedural mechanisms have been presented to the ITU-R that could satisfy established fault monitoring and reporting requirements and ensure that MSS (space-to-Earth) signals would not have an negative effect on the continuity of flight operations.

The ITU-R examined the matter of burden sharing between ARNS/RNSS and the MSS (space-to-Earth) and concluded that the burden sharing concept is not applicable in the 1 559-1 610 MHz band, particularly due to the fact that ARNS/RNSS are safety services.

2.2.2 Band 1 675-1 710 MHz

This section addresses the area of Resolution **213 (Rev.WRC-95)**, which calls for completion of technical and operational studies of the feasibility of sharing between the MSS (Earth-to-space) and the MetSat (space-to-Earth), MetAids, FS and MS services.

2.2.2.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

The ITU-R has completed studies regarding the feasibility of sharing in the 1 675-1 710 MHz band between the MSS and MetSat and produced a draft revision of Recommendation ITU-R SA.1158-1. The studies considered the different uses of this band by the MetSat service in three sub-bands and came to the conclusions below. Regarding the MetAids service, Recommendation ITU-R SA.1262 analyses the feasibility of sharing between MSS and MetAids services in the band 1 675-1 700 MHz.

2.2.2.2 Analysis of the results of studies

2.2.2.2.1 Study results regarding sharing between MSS and MetAids

Regarding the MetAids service, sharing studies completed to date indicate that co-channel sharing between currently proposed MSS systems and MetAids operated in the band 1 675-1 700 MHz is not feasible due to unacceptable levels of interference to MetAids systems and non-GSO MSS systems. While the GSO MSS systems may be able to accept interference levels from MetAids, the protection to MetAids from mobile earth stations is required according to No. **S5.377**. It should also be noted that cross-border coordination would be required between mobile earth stations and MetAids when such different uses are made of parts of this spectrum in neighbouring countries. Studies also indicate that time sharing is not feasible due to the nature of both services. Studies have concluded that co-frequency sharing between MetAids and MetSats in the band 1 675-1 700 MHz is not feasible. In view of the thousands of meteorological earth stations in the band 1 690-1 700 MHz, MetAids operations have to be restricted to the sub-band 1 675-1 690 MHz, where significantly less MetSat stations are deployed. Coordination is required between MetAids operators and MetSat earth stations in Region 2 and Region 3 due to unacceptable levels of interference in the range 1 683-1 690 MHz, where GVAR (GOES Variable) (Region 2) and S-VISSR (Stretched - Visible and Infrared Spin Scan Radiometry) (Region 3) operations occur.

WMO identified future requirements for narrow-band MetAids operations as 1 675-1 683 MHz, while wideband MetAids requirements for some administrations should not exceed 12 MHz consistent with national spectrum availability. Consequently, some of the administrations with wideband MetAids requirements in Regions 2 and 3 will also require spectrum in the range 1 683-1 690 MHz.

2.2.2.2.2 Study results regarding sharing between MSS and MetSat

Regarding the sharing situation between MetSat and the MSS, the following conclusions have been reached for the three different sub-bands considered.

a) 1 675-1 690 MHz band

Sharing is considered feasible if an appropriate separation distance is kept at all times between MetSat and MSS earth stations, as determined pursuant to coordination under No. **S9.11A**. Studies have shown that typical separation distances would be up to 55 km for non-GSO MSS systems and up to 70 km for GSO MSS systems. The mobile earth station locations will have to be determined with sufficient accuracy relative to the required separation distances. Coordination of mobile earth stations in this band would therefore be subject to the ability of MSS systems to respect these separation distances through location determination capabilities. The number of MetSat earth stations deployed in the three Regions is significantly different. There are relatively few main stations deployed in all three Regions. In addition, there is a large number of meteorological GVAR/S-VISSR satellite earth stations in Regions 2 and 3 in the range 1 683-1 690 MHz. Coordination with these earth stations will also be required and sharing may not be possible in those countries where a large number of these stations is deployed.

b) 1 690-1 698 MHz band

Sharing of this sub-band is not feasible due to the existence of many thousands of earth stations receiving data from geostationary meteorological satellites.

c) 1 698-1 710 MHz band

The sharing situation is very complex in this sub-band and various problems must be considered. Sharing based on exclusion zones (separation distances) is not feasible due to the large number of MetSat earth stations and their generally unknown locations. Nearly a thousand MetSat earth stations already are deployed in this band. It is expected that this number will increase significantly because a number of new MetSat systems are planned for this band. Sharing based on time separation will be subject to severe operational and design constraints on the MSS as well as strong interference from MetSat satellites. It can be generally concluded that the band cannot be used by the MSS itself but must be considered at most as an extension band to another allocated band as the available bandwidth drops to zero at irregular time intervals. A study based on a model with 14 meteorological satellites revealed that availability of bandwidth would be of short duration and frequently inadequate to provide access during the entirety of a normal telephone call. Consequently, only variable bandwidth, short duration data transmission would be possible in such a situation. Increasing the number of meteorological satellites would result in decreased availability of bandwidth and time due to the required phasing of the meteorological satellites in order to minimize internal interference. Any use of this band would require continuing real-time coordination involving between ten and twenty active MetSat satellites operated by different administrations or international organizations already within the next decade. Furthermore, the difficulties of implementing timesharing would be enormous due to the need to maintain precise current information on the position and current frequency usage of MetSats in the band. MSS systems will suffer additional constraints when MetSats transmit wideband signals toward their corresponding CDA stations. Detailed studies on this subject have not been done, but the already limited availability of spectrum will be further reduced. Taking all these into account, it is considered very difficult that MSS operation of a viable system within this band could comply with No. **S5.377**. For the above reasons, sharing of this sub-band should not be considered.

The band 1 700-1 710 MHz is also allocated to the FS on a co-primary basis and is used extensively by some administrations. Some of these administrations use this band for broadcasting relays. No sharing studies have been carried out yet.

2.2.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

Segmentation of the band 1 675-1 690 MHz consistent with No. **S5.377** on a national or regional basis, may be a method of providing MSS spectrum in the sub-band 1 683-1 690 MHz where no MetAids operations take place. In addition, appropriate separation distances will be required between MetSat and MSS earth stations in the sub-band 1 683-1 690 MHz, as determined pursuant to coordination under No. **S9.11A**. Coordination of mobile earth stations with relatively few MetSat main earth stations in all Regions will be required. In a number of administrations, coordination will additionally be required with meteorological GVAR/S-VISSR satellite earth stations in Regions 2 and 3 in the range 1 683-1 690 MHz. Sharing may not be feasible in those countries where a large number of these stations are deployed. Sharing must also be based on the proposed amendment to No. **S5.377** in § 2.2.2.4 and take into account the different use of this band in the three ITU Regions by the MetSat service.

2.2.2.4 Regulatory and procedural considerations

Protection of the MetSat service in the band 1 683-1 690 MHz could be ensured by a proper footnote supplementing the provisions of No. **S5.377** for which the following text should be considered:

"Mobile-satellite systems using the 1 683-1 690 MHz band shall not cause harmful interference to earth stations of the meteorological-satellite service. To avoid causing harmful interference, mobile earth stations shall not operate, except in a non-interfering signalling channel, within the exclusion zones around the meteorological earth stations defined in Recommendation ITU-R SA.1158-1(Rev.). The mobile-satellite system shall have position determination capabilities to ensure compliance with this provision."

****

2.3 Agenda item 1.11

"to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-GSO/MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions **214 (Rev.WRC-97)** and **219 (WRC-97)**"

2.3.1 Constraints on existing allocations for the non-GSO MSS below 1 GHz (Resolution 214 (Rev.WRC-97))

2.3.1.1 Summary of technical and operational studies relevant to constraints on existing allocations and relevant to sharing between existing non-GSO MSS systems and existing terrestrial services

A number of studies have been carried out since MSS allocations for non-GSO satellite systems were first agreed at WARC-92. These have led to ITU-R Recommendations that indicate the sharing techniques, which are being used by those systems to share with each other and other co-primary services.

2.3.1.2 Analysis of the results of studies

Table 1 from Recommendation ITU-R M.1389 summarizes the techniques and Recommendations applied to existing MSS allocations. Many of these techniques are being employed in practice successfully.

2.3.1.3 Method to satisfy the agenda item

The constraints on existing allocations are reflected in the footnotes to the allocations, and in Appendix **S5** and No. **S9.11A**. These have evolved to their present form since WARC-92. Administrations have accepted the sharing criteria between services of equal status.

These constraints have served to provide a basis for implementing non-GSO MSS systems in these bands and at the same time provide protection to other space and terrestrial services. Therefore in respect of the constraints on the MSS in existing allocations below 1 GHz, no further modifications are needed.

2.3.1.4 Regulatory and procedural considerations

No modifications are required to the tables of criteria applicable to MSS allocations for use by non-GSO systems below 1 GHz, as found in No. **S9.11A**, or to the footnotes containing constraints that apply to the pertinent allocations.

2.3.2 Studies on non-GSO MSS links (Earth-to-space) sharing with terrestrial services in the band 450-470 MHz (Resolution 214 (Rev.WRC-97))

2.3.2.1 Summary of technical and operational studies

The ITU-R conducted sharing studies relevant to possible additional Earth-to-space allocations to the non-GSO MSS during the ITU-R study period 1996-1997 and the current study period 1998-1999. A variety of scenarios were examined with differing technical characteristics for systems in the mobile and fixed services and for mobile-satellite systems.

Study 1

In specific studies conducted at 460 MHz, interference between a non-GSO MSS network and land mobile systems was analysed. The MSS network used was a 48 satellite system with the characteristics of the system designated LEO-L in draft revision of Recommendation ITU-R

M.1184[8/47]. The land mobile system was modelled with the following characteristics: an analogue, frequency modulation system (or digitally modulated, binary-FSK system); a vertically polarized antenna having 0 dBi gain towards the satellite; 10 m^2 antenna height product (consistent with Recommendation ITU-R M.1039-1(Rev.)[8/53]); minimum received signal power assumed to be -140 dBW; and channel bandwidths of 6.25, 12.5 and 25.0 kHz. Several worst-case assumptions were made: 1) non-GSO MSS mobile earth stations (MESs) transmitting at 100% of network capacity, 24 hours per day, 2) terrestrial stations and non-GSO MESs geographically clustered in the same areas, and 3) dynamic channel avoidance not employed. For the conditions modelled in these studies, it was calculated that the probability of interference to a land mobile receiver resulted in less than 0.1% decrease in channel availability, that is, a reduction in channel availability smaller than a 99% availability being reduced to 98.9%. Over the range of parameters studied, the mean time between interference events for a land mobile user with 0.01 Erlangs of traffic was calculated to range from 10 hours to 21 months, which is much less than 0.1% decrease in channel availability. Since in general the non-GSO MSS network would be able to identify and avoid active mobile channels, the actual interference from non-GSO MSS MESs into the modelled land mobile station would be much less than that calculated under the worst-case assumptions used in the analysis.

In these same studies at 460 MHz, the availability of temporarily clear land mobile channels that could be used for MES uplinks was determined. These studies showed that a sufficient number of clear channels per satellite (six for the MSS network used) could be found with a density of use by the land mobile systems ranging from 77 000 to 190 000 mobile stations within the satellite beam (12 million km^2) in 1 MHz of shared bandwidth. In 5 MHz of shared bandwidth, six available clear channels could be found with 570 000 to 1.5 million terrestrial mobile stations operating within the satellite beam.

Study 2

Other specific studies evaluated non-voice, non-GSO MSS networks frequency sharing with the fixed and mobile services operating in a portion of the band 450-470 MHz. The MSS networks modelled had characteristics of the 81 satellite "LEO-T" network described in draft revision of Recommendation ITU-R M.1184[8/47]. The mobile system was modelled with the following characteristics: analogue FM or digital modulation; 5 dBi antenna gain toward the horizon; 200 m antenna height resulting in an antenna height product of 600 m^2; C/(I+N) of 17 dB and channel bandwidths of 16 and 25 kHz. These analyses indicate that sharing in portions of the 450-470 MHz band is feasible subject to certain operational constraints on the non-voice, non-GSO MSS networks; such constraints include MES transmission duration and transmission duty cycle limitations. It is concluded that shared access to a minimum of 4 MHz of spectrum by five non-voice, non-GSO MSS can meet the modelled land mobile service (LMS) protection requirements. This conclusion is based on the conditions that: any single MSS MES transmission must be less than 450 ms in duration, and: an individual MES cannot retransmit on the same frequency within a 60 s period.

In addition, these studies assumed the following traffic loading rates:

Mobile:	0.01 Erlang
Base Station:	0.733 Erlang
Fixed Station:	0.6 Erlang

It has been determined that by imposing the above technical constraints on the MSS, the operational needs of the modelled non-voice, non-GSO MSS operating in portions of the 450-470 MHz band are satisfied while at the same time meeting the FS and LMS performance objectives. The use of Dynamic Channel Assignment Techniques such as described in Recommendation ITU-R

M.1039-1(Rev.)[8/53] may also be used by low power, low duty cycle non-voice, non-GSO MSS systems to further reduce the probability of interference and promote compatibility with terrestrial services.

Study 3

An analysis was performed at 455 MHz to evaluate frequency sharing between FDMA narrow-band uplinks in the non-GSO mobile-satellite service and a specific terrestrial system operating in a mobile service band. The non-GSO MSS network modelled had 48 satellites with Earth-to-space links from mobile earth stations with antenna heights of 3 m. The satellite network was assumed to use a dynamic channel assignment technique to avoid channels that were actively being used by terrestrial systems, and it was assumed that this channel assignment technique was 99.8% effective in detecting active remote pickup unit (RPU) channels for the specific terrestrial systems modelled.

The specific terrestrial system was an RPU linked to a sound broadcasting station, in an urban noise environment (assumed to be -138 dBW). The remote unit antenna height was 15 m and the base station receiving antenna height was 60 m. The simulation results showed that the probability of interference was 0.00015% (due to one interfering non-GSO MSS system). This is equivalent to a single short, one-half second, interference event every four days, assuming that the RPU is operating continuously for that period. If the RPU only operated for 2.5 hours per day, then the average interval between short, one-half second, interference events would be a month. The results show that for the particular sharing scenario analysed the RPU channel availability was degraded by much less than a 99% availability being reduced to 98.9%.

Study 4

Studies of sharing between an MS system and two example digital terrestrial systems in the band 450-470 MHz have been carried out, investigating the probability of interference from the MSS MES to the mobile units and the base stations of the terrestrial systems. The analyses at 455 and 460 MHz modelled a non-GSO MSS network with 48 satellites and narrow-band Earth-to-space links from mobile earth stations with antenna heights of 3 m. This is the MSS system designated as LEO-L in draft revision of Recommendation ITU-R M.1184[8/47]. MES data rates of 9.6, 4.8, and 2.4 kbits/s were used. Base station to mobile and mobile to base station links using transmitter and receiver characteristics from two digital trunked land mobile systems were modelled:
1) characteristics that were provided by ITU-R for a system that may be installed in many Region 1 and other countries, and 2) characteristics that were provided by ITU-R for a system similar to those used in a Region 2 country. The links of the first used digital modulation, 25 kHz channel spacing, 1.5 m mobile antenna height with 45 dBm transmitter power, and 50 m base station antenna height with 40 dBm transmitter power. The second system used digital modulation, 6.25 kHz channel spacing, 2 m mobile antenna height with a maximum of 38.5 dBm transmitter power, and 200 m base station antenna height with 48 dBm transmitter power. The threshold of interference in both cases was a carrier-to-interference ratio less than 19 dB. The statistical simulation model in draft revision to Recommendation ITU-R M.1039-1(Rev.)[8/53] was used to determine the probability of interference to digital trunked receivers at mobile and base locations. Four different geographical regions were used in the studies, Europe, North America, South America, and Central America & Caribbean. For the range of parameters studied, the maximum probability of interference into a single terrestrial link was 0.0030% for the first system and 0.0027% for the second system. The

higher value is equivalent to a single, half-second interference event occurring once every four hours at a continuously operating LMS receiver. The results may be viewed as 99% channel availability being reduced to 98.9970% for the highest probability of interference in the cases studied. The parameters provided for these studies do not take into account the network design and other considerations of digital trunked systems, and therefore do not account for network aspects of sharing in the band.

Other studies

There are many kinds of terrestrial systems operating in the band 450-470 MHz which have varied technical and operational requirements (such as density distributions, necessary C/(N+I) ratios and antenna heights). Therefore, at this time, it might be difficult to provide single value protection or sharing criteria applicable to all such systems. It may be necessary to do case-by-case studies of specific combinations of systems and bands and a number of such studies have been performed. The following are the results of interference studies of several systems within one administration calculated by using the methodology contained in Recommendation ITU-R M.1039-1(Rev.)[8/53].

Some fixed radio frequency links designed for government use, including public safety are, in case of emergency, occupied as much as 80% of the time. The transmitting power towards a non-GSO satellite could be as low as 0.028 Watts for brief periods of time, which may not be sufficient for instantaneous detection by a Dynamic Channel Assignment Technique system. Low power devices, such as wireless microphones and leaky coaxial cable communication systems, may also be of insufficient power for detection by Dynamic Channel Assignment Technique.

Studies were performed on two kinds of land mobile wireless systems used by broadcasting utilities. One of these systems is used in one administration for monitoring of incoming signals 24 hours per day at base stations located at an altitude of up to 1 000 m. Additional interference due to MES transmissions in the presence of a waiting mode receiver may increase the number of times that the squelch is activated and decrease the lifetime of the squelch relay to some extent. Some MES transmissions may be too short to activate the squelch circuit.

Further, because it is expected that the signals received at the satellite will experience scintillation in the frequency band 450-470 MHz (Recommendation ITU-R P.531), MSS systems may need to be designed to account for this.

2.3.2.2 Analysis of results of studies

Studies conducted by the ITU-R show the low probabilities of interference resulting from co-channel sharing between narrow-band, FDMA MSS uplinks and terrestrial services for different specific cases. For frequencies near 460 MHz, both analogue and digital terrestrial systems were analysed. In cases with certain LMS receivers with antenna heights of 1.5 m, 3 m, 50 m, 60 m and 200 m, the probabilities of MSS mobile earth stations interfering into terrestrial receivers were shown to be less than 0.1%, which would meet an availability criteria of no greater than 0.1% decrease in availability when appropriate technical and operational constraints, such as dynamic channel assignment techniques were used. Analyses showed that for co-channel sharing between terrestrial services with assumed characteristics and the MSS below 1 GHz, the probability of interference decreased with increasing shared bandwidth. Also the use of short duration, intermittent signals by the MSS uplinks contributed to the low probabilities of interference.

Sharing studies investigating interference effects to and from future digital terrestrial systems, as well as in a mixed digital/analog and other specific environments remain to be completed.

2.3.2.3 Methods to satisfy the agenda item

Because of the heavy use of frequencies below 1 GHz by presently allocated services and the possibilities of co-channel sharing with the existing services, the ITU-R has not identified additional frequency bands for exclusive use by non-GSO MSS Earth-to-space links.

However, the results of specific ITU-R technical studies indicate that additional allocations to the non-GSO MSS below 1 GHz (Earth-to-space) may be achieved in some cases by the following methods:

- co-frequency allocations to the non-GSO MSS and the terrestrial services near 460 MHz may provide sufficient channels for MSS uplinks and low interference probabilities to the existing services noting that network aspects of digital trunked systems in the band have not been taken into account, thus further study is required in the area of sharing between digital trunked systems and MSS. Further studies are also needed for the mobile and fixed systems described in section 2.3.2.1 - Other studies;
- appropriate technical and operational constraints on the non-GSO MSS networks (as used in the studies) would be required to keep the probabilities of interference to the existing services to acceptable levels.

2.3.2.4 Regulatory and procedural considerations

Additional allocations to the non-GSO MSS below 1 GHz for Earth-to-space links in bands shared with MS and FS allocations need to ensure that the existing services are provided with acceptable levels of protection against possible interference. Recommendation ITU-R M.1039(Rev.)[8/53] addresses the use of dynamic channel activity assignment techniques by MSS systems to avoid the use of channels that are in active use by terrestrial systems. Recommendation ITU-R M.1039(Rev.)[8/53] also notes that restrictions on the MSS length of transmissions and on the re-use of frequencies in the same location can facilitate sharing with certain terrestrial services used for voice communications. Since non-GSO MSS sharing with the existing allocations depends on MSS systems using these characteristics, appropriate restrictions would need to be applied to any new allocations to the non-GSO MSS.

Current allocations to the non-GSO MSS near 460 MHz (454-456 MHz and 459-460 MHz) are restricted to Region 2 and to several administrations in each of the other two ITU Regions. These regional or country allocations limit the use of MSS networks to these areas. For the non-GSO MSS networks, worldwide allocations to the MSS would allow the use of the satellite network resources by all parts of the Earth.

2.3.3 Resolution 219 (WRC-97) "Studies relating to consideration of the allocation to the non-geostationary mobile-satellite service in the meteorological aids band 405-406 MHz and the impact on primary services allocated in the adjacent bands"

2.3.3.1 Summary of technical and operational studies including a list of relevant ITU-R Recommendations

Sharing studies carried out by ITU-R indicate that co-channel sharing between non-GSO MSS systems using narrow-band modulation techniques and MetAids service in the band 401-406 MHz is not feasible.

ITU-R has also completed studies regarding the use of the MetAids band and developed a draft revision to Recommendation ITU-R SA.1258-1 and Recommendation ITU-R SA.1165-1. The studies conducted by several administrations and by WMO considered the worldwide spectrum requirements in this band for radiosonde systems in the MetAids service and for data collection systems in the EESS and the MetSat service.

ITU-R has carried out some studies regarding the protection of Cospas-Sarsat services in the band 406-406.1 MHz and radio astronomy services in the band 406.1-410 MHz. Recommendation ITU-R M.[8/84] contains protection criteria for SARSAT search and rescue processors (SARP) in the band 406-406.1 MHz.

2.3.3.2 Analysis of the results of studies

2.3.3.2.1 Current and future use by EES/MetSat

At WRC-97 the band 401-403 MHz was upgraded as a primary allocation to the EES/MetSat service. This band is used for the operations of Data Collection Systems (DCS) on GSO and non-GSO MetSat/EES satellites. DCS Data Collection Platforms (DCP) make periodic measurements of a wide range of environmental data and uplink them to the MetSat/EES satellite. Alert DCPs are also installed to report emergencies and data from hazard/disaster recognition. Sharing between DCPs and MetAids is currently being accomplished via careful coordination within the operating agencies of meteorological services.

Recommendation ITU-R SA.1258-1-contains sharing criteria between MetSat, EES and MetAids services in the band 401-403 MHz. Co-channel sharing of MetAids with non-GSO MetSat/EES (currently operating in 401-402 MHz) is not feasible; co-channel sharing of MetAids with GSO MetSat is difficult or not feasible in some areas. A WMO survey shows that DCP stations are expected to significantly increase in number for the foreseeable future and this will result in a segmentation of the band 401-406 MHz between EES/MetSat and MetAids services. It is anticipated that the MetAids service may effectively have only the 403-406 MHz band available in the future.

2.3.3.2.2 Current and future requirements for MetAids

Radiosonde observations are vital for operational meteorology (weather analysis, warnings and forecasts), coordinated in the framework of WMO, and for several other applications (research, environmental, defence).

There are increasing requirements for MetAids operation for meteorological, research, environmental and defence applications. MetAids services need all of the band of 403-406 MHz, and part of the band 401-403 MHz under adequate sharing coordination with EES/MetSat, where feasible.

At WARC-92, the portion of the spectrum band 400.15-401 MHz was allocated to the MSS, and National Meteorological Services plan to move narrow-band MetAids operation out of the band to enable MSS operation.

The technical characteristics and performance criteria for radiosonde systems in the MetAids service are given in Recommendation ITU-R SA.1165-1. In the long term, improved technology and operational techniques may result in more efficient use of these bands and more affordable radiosondes, which may enable future review of requirements for the band 401-406 MHz. These improvements would facilitate the increasing usage of MetAids service in those countries with increasing requirements that can bear the significant increase in costs of new radiosondes. The use of advanced spectrum-efficient meteorological aids systems has already been implemented in a few countries in order to meet requirements for high density MetAids networks within the existing allocations, but at very high costs.

For most of the countries, and in particular for developing and less-developed countries, the use of more spectrum efficient meteorological aids systems would increase the operational costs of meteorological aids networks beyond the available financial resources, and would damage current meteorological operations and hamper the future development of radiosonde measurements.

Data collected by MetAids in any country benefits all member nations of the WMO by providing essential data for weather analysis, warnings, forecasts and climate change studies.

Taking into account current technology, transition of the MetAids service out of the band 405-406 MHz is considered as not feasible in order to accommodate the increasing requirements for EES/MetSat in the band 401-403 MHz, and the increasing requirements of MetAids in the band 401-406 MHz, taking into account sharing constraints between MetAids and EES/MetSat. This conclusion also takes into account the economic viability of MetAids improvements in spectrum efficiency.

2.3.3.2.3 Impact on primary services in adjacent bands

a) Impact on Sarsat SARP in the band 406-406.1 MHz

The results of analyses indicate that the required protection level for Sarsat Search and Rescue Processor (SARP) operations in the band 406.0-406.1 MHz is -198.6 dB(W/(m^2·Hz)) against out-of-band broadband emissions, and pfd -185.8 dB(W/m^2) against spurious narrow-band emissions. The analyses also indicated that the Doppler shift should be considered in determining the effect upon Cospas-Sarsat instruments by proposed MSS using the 405-406 MHz band (the worst-case Doppler shift is 20 kHz).

The results further indicated that possible future use of the band 405-406 MHz by non-GSO MSS will require a guardband at the upper band edge that may extend from 61 to 142 kHz in order to limit interference to the Sarsat SARP.

b) Impact on Cospas SARP in the band 406-406.1 MHz

The results of analyses indicate that the required protection level for Cospas Search and Rescue Processor (SARP) operations in the band 406.0-406.1 MHz is -200.8 dB(W/(m^2·Hz)) against out-of-band broadband emissions, and pfd is -176.6 dB(W/m^2) against spurious narrow-band emissions. The analyses also indicated that the Doppler shift should be considered in determining the effect upon Cospas-Sarsat instruments by proposed MSS using the 405-406 MHz band (the worst-case Doppler shift is 20 kHz).

The analysis results further indicated that possible future use of the band 405-406 MHz by non-GSO MSS would require a guardband at the upper band edge that may extend from 32 kHz, as a minimum, in order to protect from a burn out of the low noise amplifier of the Cospas SARP.

c) Impact on radio astronomy service in the band 406.1-410 MHz

The band 406.1-410 MHz is allocated on a primary basis to radio astronomy, to be shared with fixed/mobile services under No. **S5.149**. This band is used for continuum mode observations leading to sky surveys and study of pulsars. The band is extensively used in many radio observatories around the world. In Canada, observations in this important radio astronomy band are made 100% of the time.

As listed in Recommendation ITU-R RA.769-1, the threshold detrimental level to RAS on the ground in the 406.1-410 MHz band is -255 dB(W/(m^2·Hz)). The maximum pfd level at the ground for MSS transmissions is -161 dB(W/(m^2·Hz)). Thus, the required MSS signal attenuation to protect RAS is 94 dB. This required attenuation is appropriate only to an emerging technology and is not characteristic of existing satellites. It is understood that the MSS system planned under the proposed allocation is employing a small number of satellites to minimize the probability of interference by satellites passing near the main beam of a radio telescope.

This attenuation might be attainable through a combination of spectral shaping techniques, centre frequency offset and transmit filtering on the proposed MSS service. A guardband near the upper band edge for the proposed MSS operations in the 405-406 MHz band will be essential. The width for the guardband is to be decided based on practical aspects of continued protection to radio astronomy during the lifetime of the satellite.

2.3.3.3 Methods to satisfy the agenda item and the advantages and disadvantages

Method A: Allocation to the MSS

Allocate the band 405-406 MHz to the non-GSO MSS, with a transition of MetAids out from the band 405-406 MHz, while ensuring the protection of Cospas-Sarsat systems and radio astronomy service.

Advantage

The new allocation would provide additional spectrum available for non-GSO MSS systems below 1 GHz.

Disadvantages

- The transition of MetAids out from the band would be required to enable MSS operation. For the foreseeable future, it would damage current MetAids operations (meteorological, environmental and defence) and hamper future MetAids service development.
- The protection of Cospas-Sarsat in the band 406-406.1 MHz and the radio astronomy service in the band 406.1-410 MHz requires protection limits and an upper guardband for MSS systems.

Method B: No change to current allocations

Maintain current allocations of 401-406 MHz.

Advantage

Maintaining current allocations would protect the MetAids service and would enable EES/MetSat and MetAids to meet increasing service requirements.

Disadvantage

Does not provide urgently needed spectrum for MSS below 1 GHz, in the candidate band 405-406 MHz.

Summary

Operation of the MSS in the band 405-406 MHz (Method A) is considered as not feasible in the foreseeable future_based on assessments and studies carried out by ITU-R. Studies on improved technology and operational techniques may result in the long term in more efficient use of these bands, and may enable future review of requirements for the band 401-406 MHz and some administrations are continuing studies in this area.

2.3.3.4 Regulatory and procedural considerations

If an allocation were to be made in a portion of the band 405-406 MHz to MSS, protection limits would need to be included into the Radio Regulations to provide adequate protection measures to Cospas-Sarsat (Recommendation ITU-R M.[8/84]) and radio astronomy (Recommendation ITU-R RA.769-1).

****

2.4 Agenda item 1.15

"issues related to the radionavigation-satellite service"

2.4.1 Agenda item 1.15.1

"to consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments"

Current designs of proposed RNSS systems operate with restrictions on the signal bandwidth and limitations on the achievable performance. The evolution towards and beyond Global Navigation Satellite System-2 (GNSS-2) would be better assured by the provision of additional allocations for RNSS.

Current RNSS systems using frequencies in the bands 1 215-1 260 MHz and 1 559-1 610 MHz are significantly affected by variable delays due to electron fields in the ionosphere, with the result that accurate navigation requires the use of measurements at local stationary reference points with accurately-known locations and communication of these measurements to the (moving or stationary) object under survey. Moreover, the higher frequencies also permit higher accuracy in tracking of the RNSS satellites.

Wider signal bandwidth would allow higher code rates to give better navigation accuracy and reduce multipath errors, which would benefit all RNSS applications. An RNSS network in the frequency range 1 GHz to 6 GHz is considered to require between 20 to 24 MHz of spectrum. If other networks must be considered, a wider allocation might be necessary, unless compatible designs could be introduced which would allow co-frequency sharing.

Studies are therefore being made into the feasibility of RNSS systems using frequencies, which are high enough to reduce the effects of ionospheric delay, or significantly different from existing RNSS signals to allow for correction of ionospheric delay, but which are not so high as to suffer significant troposphere attenuation. Such systems would require a sufficient RNSS (space-to-Earth) allocation.

Proposals for RNSS systems have been made in which the satellites are required to be synchronized to terrestrial beacon reference stations. Less than 50 beacons are required, distributed worldwide. These proposals would require an RNSS (Earth-to-space) allocation. The corresponding downlinks are in the already existing RNSS (space-to-Earth) allocations 1 215-1 260 MHz and 1 559-1 610 MHz.

Another proposal considers an RNSS (space-to-Earth) signal in a portion of the 960-1 215 MHz aeronautical radionavigation service (ARNS) band. A new RNSS allocation should provide for new

Global Navigation Satellite System (GNSS) signals that can be used, together with a signal in the 1 559-1 610 MHz band, to mitigate ionospheric delay errors; provide robustness in the event of unintentional interference; and reduce the time required to resolve carrier phase ambiguities. It is anticipated that the new RNSS signals will be used for many aviation and non-aviation applications.

The band 960-1 215 MHz is being used for a variety of aeronautical radionavigation systems as further specified in § 2.4.1.1.1. The use of these systems and their enhancements is expected to continue for the next two decades without any expectation of any decrease.

2.4.1.1 Summary of technical and operational studies

2.4.1.1.1 RNSS (space-to-Earth) in part of the band 960-1 215 MHz

The 960-1 215 MHz band is allocated to the ARNS on an exclusive, worldwide basis and is used for ICAO standardized radionavigation and surveillance systems that include: the Secondary Surveillance Radar (SSR), the Airborne Collision Avoidance System (ACAS) and the Distance Measuring Equipment system (DME) and is also used for the Tactical Air Navigation system (TACAN). The 1 151-1 215 MHz portion of that band is used by ground DME and TACAN transponders.

A study has shown that a bandwidth of 24 MHz could allow the requirements for Category I/II/III aircraft precision approach to be met, and will improve GNSS services to land-based, maritime, and airborne users worldwide.

A study was performed to assess the compatibility of a signal in the proposed RNSS band with the aeronautical radionavigation receivers in the 960-1 215 MHz band. The study concluded that RNSS signals can be designed that do not cause interference to the inband aeronautical radionavigation receivers which include: SSR interrogators, SSR transponders, Mode S Interrogator, Mode S transponders, TCAS, TACAN/DME interrogators, and TACAN/DME transponders.

A study was performed to assess the compatibility of an RNSS signal in the band 1 164-1 188 MHz with radar receivers in the 1 215-1 400 MHz band characterized in draft new Recommendation ITU-R M.[8/118]. The study concluded that RNSS signals can be designed that do not cause interference to the adjacent band radar systems which include: aeronautical surveillance radar and air traffic control radar.

Studies were performed to assess the compatibility of the aeronautical radionavigation transmitters operating in the 960-1 215 MHz band and GNSS receivers using a new RNSS signal in 1 151-1 215 MHz. Initial studies conclude that:

a) Measures could be taken to ensure that emissions from equipment on board aircraft transmitting in the band 1 025-1 150 MHz and spurious emissions from other on board equipment into RNSS receivers in the band 1 164-1 215 MHz on board the same aircraft would be tolerable. Moreover, ICAO has stated that any such on board compatibility is considered an internal aviation and industry matter. It is considered unlikely that such emissions would affect RNSS receivers on the ground.

b) RNSS networks in the band 1 164-1 188 MHz can be designed so that their receivers can tolerate interference due to emissions from radar stations operating in the band 1 215-1 400 MHz. Considering that RNSS systems currently operate in the band 1 215-1 260 MHz, a similar result is expected for RNSS receivers in the band 1 151-1 215 MHz, though a guardband may be required for certain applications.

c) In certain geographical areas where there is a high density of ground-based DME transponders, harmful in-band interference would be received by wideband RNSS receivers on aircraft at high altitude. One proposed solution is frequency re-assignment of some co-frequency DME/TACAN transponders in these areas, but this is not feasible in some of these areas due to lack of available DME channels. Another proposed solution is use of a dual-bandwidth RNSS signal, avoiding interference at high altitudes by use of a narrow-band signal component while obtaining the precision required at lower altitudes by use of a wideband signal component.

d) Ground-based RNSS receivers can be designed to tolerate the interference from ground-based DME transponders.

e) Sharing of the same spectrum by two or three different RNSS networks, which would minimize the necessary allocation, has been shown to be technically feasible and to result in only a slight increase in the interference received by the RNSS receivers of each network. However, this would require compatible power levels and signal types in the design and operation of the different RNSS networks. Use of independent spectrum by each RNSS network would decrease the chance of a single interference incident affecting more than one network.

It was recognized that, if an allocation to RNSS were to be made in any part of the band 960-1 215 MHz, further study effort will be required by ITU, ICAO and others to develop Recommendations to ensure compatibility between the various systems in the band.

2.4.1.1.2 RNSS (space-to-Earth) in the band 1 260-1 300 MHz

In principle, there is no major difference between the current allocations of 1 215-1 260 MHz and 1 260-1 300 MHz apart from the absence of RNSS from the latter.

The band 1 260-1 300 MHz, as the band 1 215-1 260 MHz, might provide scope for non-aeronautical, non-safety-of-life radionavigation-satellite applications, without operational constraints on terrestrial radar and spaceborne synthetic aperture radar installations.

The band 1 260-1 270 MHz is allocated to the amateur satellite service.

Wind profiler radars are planned to use the band 1 270-1 295 MHz, and these have a higher duty cycle (10%) than other radars, so that multiple-entry interference, if it occurs, may cause problems.

2.4.1.1.3 RNSS (space-to-Earth) in parts of the band 5 000-5 150 MHz

a) Protection of the radio astronomy service (RAS) allocation in the band 4 990-5 000 MHz

Studies have shown that a guardband of at least 10 MHz is required between an RNSS (space-to-Earth) allocation and the RAS band immediately below 5 000 MHz together with careful control of the RNSS out-of-band emissions.

A study has shown that filters can be designed which provide enough attenuation to easily accommodate the protection requirements of the RAS contained in Recommendation ITU-R RA.769-1 within the RAS allocated bands.

b) Protection of the MLS system in the band 5 030-5 091 MHz and 5 091-5 150 MHz

An RNSS (space-to-Earth) system operating in the 5 010-5 030 MHz band is compatible with MLS operations in the band 5 030-5 150 MHz if its power flux-density at the surface of the Earth does not exceed the level of -124.5 dB(W/m^2) in a 150 kHz band, as specified by ICAO.

Analysis has shown that sharing in the band 5 030-5 150 MHz with MLS is not feasible due to unacceptable interference from MLS to RNSS receivers up to the radio horizon.

c) Sharing with feeder links in the band 5 091-5 150 MHz

The band is allocated to the FSS (Earth-to-space) for use by MSS feeder links under the conditions of No. **S5.444A**.

Analysis has shown that sharing of the band between RNSS (space-to-Earth) and FSS (Earth-to-space) is not feasible due to unacceptable interference from feeder links to RNSS receivers up to the radio horizon.

d) Sharing with AMS(R)S in the band 5 000-5 150 MHz

The band 5 000-5 150 MHz is allocated to AMS(R)S through No. **S5.367**. This band is currently unused by AMS(R)S and no studies have been carried out on sharing between AMS(R)S and RNSS in the band 5 000-5 150 MHz.

2.4.1.1.4 RNSS (Earth-to-space) in parts of the bands 1 300-1 350 MHz or 5 000-5 030 MHz

a) Sharing with radionavigation and radiolocation in the band 1 300-1 350 MHz

RNSS beacons using the band 1 300-1 350 MHz will be located in areas permitting their operation above 15° elevation for any azimuth. In addition, an antenna decoupling of at least 50 dB will be provided at elevation angles lower than 10° through the use of choke-ring equipment. In this context, analyses have shown that a separation distance of 60 km or less, depending on the radar to be protected, is sufficient to avoid excess interference of RNSS (Earth-to-space) beacons into radars. Considering the small number of these radiobeacons (less than 50 worldwide), the choice of their location, taking this constraint into account, is not problematic. On the other side of the problem it was shown that with an adequate tuning of the AGC loop in the receiver, the interference of radionavigation and radiolocation radar in the band 1 300-1 350 MHz is compatible with the operation of the RNSS (Earth-to-space) radiobeacon transmission.

b) Protection of the RAS allocation in the band 4 990-5 000 MHz

The RAS can be well protected through the implementation of an adequate separation distance between the beacons and the RA sites.

c) Protection of MLS in 5 030-5 091 MHz and 5 091-5 150 MHz

The MLS can be well protected through the implementation of an adequate separation distance between the radiobeacons and the MLS sites. The specific characteristics of the RNSS beacons will need to be used to determine the required separation distance from airports using or planning to use MLS. Guidance could be taken from Recommendation ITU-R S.1342.

d) Sharing with AMS(R)S in the band 5 000-5 150 MHz

The band 5 000-5 150 MHz is allocated to AMS(R)S through No. **S5.367**. This band is currently unused by AMS(R)S and no studies have been carried out on sharing between AMS(R)S and RNSS in the band 5 000-5 150 MHz

2.4.1.2 Analysis of the results of studies

New worldwide allocations to RNSS (space-to-Earth) are required to support advanced RNSS systems. The 1 151 to 1 215 MHz portion of the 960-1 215 MHz ARNS band was investigated for RNSS (space-to-Earth). Studies to date indicate that new signals in this portion of the band would not interfere with current users. The feasibility of airborne reception of RNSS signal in the current RF environment depends on careful RNSS design, and is under investigation. Preliminary sharing analyses have shown that airborne RNSS receivers are compatible with the existing environment except in certain geographic areas, and at high altitude, where a dense DME/TACAN environment is encountered by the receivers. Frequency reassignment of some ground DME/TACAN transponders would be required if high altitude use of the RNSS signal is desired in those areas and if the RNSS signal is not adapted to cope with this situation.

A new allocation to RNSS (Earth-to-space) of 20 MHz is also required to support uplink beacons. It may be possible to allocate the band 5 000-5 030 MHz to RNSS (Earth-to-space), whilst protecting the RAS allocation below 5 000 MHz. The RNSS (Earth-to-space) allocation should not be shared with RNSS (space-to-Earth) so as not to constrain the downlink. If RNSS (space-to-Earth) is allocated in the band 5 010-5 030 MHz, the RNSS (Earth-to-space) allocation should be limited to 5 000-5 010 MHz.

2.4.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

2.4.1.3.1 RNSS (space-to-Earth)

Method 1

Part of the band 960-1 215 MHz.

Advantages

- RNSS signals in this band, used in conjunction with RNSS signals in another separated band, can be used to mitigate ionospheric delay errors, to provide robustness in the event of unintentional interference and to reduce the time required to resolve carrier phase ambiguities.
- RNSS networks in this band can operate without causing harmful interference to ARNS networks.
- Wideband RNSS receivers at low altitudes or on the ground, and also in most areas at high altitudes, as well as narrow-band RNSS receivers at any altitude could be designed to tolerate the interference caused by ground-based ARNS transmitters.

Disadvantage

- In certain geographical areas where there is a high density of ground-based DME transponders, wideband RNSS receivers on aircraft at high altitude would receive harmful in-band interference, unless the RNSS system is designed to mitigate the interference.

Methods 1.1 and 1.2 are two sub-options of Method 1 for the band 960-1 215 MHz. The advantages and disadvantages mentioned above for the band 960-1 215 MHz are applicable to the sub-options below.

Method 1.1

1 164-1 188 MHz

Advantages

- In areas where administrations re-assign DME transponders to reduce the density of DME signals within the proposed RNSS band, the impact of re-assignment only affects a limited band.
- Adjacent-band interference into RNSS in this band from stations operating in the radiolocation service in the band 1 215-1 260 MHz is mitigated through a guardband.

- Three RNSS networks, with up to a total of 30 satellites in view from any location, could technically share the same band. This method thus minimizes the allocation bandwidth for RNSS and maximizes the spectrum retained for exclusive use of ARNS.
- Co-frequency operation of multiple RNSS networks enables the use of less complex common receiver equipment.

Disadvantages

- A single interference incident could simultaneously disrupt all RNSS systems within that band.
- Sharing of the same frequency band by different RNSS networks would impose technical and operational constraints on the design of each RNSS signal and would place a burden of close cooperation between all the RNSS network operators, which may have schedule, cost and design impact on both initial system implementations and subsequent modifications.
- In this band, the deployment of additional DME/TACAN transponders, as well as the development of future ARNS systems, would be hampered in certain areas.
- In the region (Europe) with the greatest interference from DME, the 1 164-1 188 MHz portion of the 1 151-1 215 MHz band has a higher density of DME compared to other portions of that band.

Method 1.2

1 151-1 215 MHz

Advantages

- Two non-overlapping 24 MHz wide RNSS networks could be implemented in the considered band, and benefit from having neither mutual constraint on their signal design, nor any requirement for permanent close common operation. This flexibility may help to design RNSS that can tolerate interference from ARNS. Much more flexibility is also given to later modification of the characteristics of the signals for an upgrade of the service.
- As a single interference incident is less likely to cause simultaneous interruption of several non-overlapping RNSS systems, these RNSS systems can provide mutual backup in the same frequency range.

Disadvantages

- In regions where administrations decide to assign DME frequencies away from the signal of any RNSS system that has not been designed to tolerate them, there is less flexibility to assign a DME to a frequency in a band that would not affect the occupied bandwidths of other RNSS systems.
- A guardband is reduced between RNSS networks operating up to the high end of the 1 151-1 215 MHz band and radar stations operating in the 1 215-1 260 MHz band, hence increasing the need for mitigation techniques for safety-of-life RNSS applications making use of that high end of the band.
- Operation of frequency separated multiple RNSS systems makes common receiver equipment more complex.

Method 2

1 260-1 300 MHz

This frequency range is currently allocated to the same primary services as 1 240-1 260 MHz except the radionavigation-satellite service (space-to-Earth). The use of the band 1 260-1 270 MHz by the amateur-satellite service operating under RR **S5.282** is also noted.

Advantage

The sharing environment is expected to be similar as in the band 1 240-1 260 MHz in which radionavigation-satellite systems are in operation under certain limitations.

Disadvantage

The use of the band by high powered radars and the related possible harmful interference to RNSS receivers leads to the conclusion that this band is not suggested for RNSS safety-of-life applications.

Method 3

Part of the band 5 010-5 150 MHz

This frequency range 5 000-5 150 MHz is currently allocated to the aeronautical radionavigation service (ARNS) and is reserved (No. **S5.444**) for the microwave landing system (MLS) on a primary basis. The 5 010-5 030 MHz portion is not included in the aviation frequency plans for MLS and is only lightly used by other ARNS systems. The 5 030-5 150 MHz portion of the band is included in the aviation frequency plan for international standard MLS systems.

The band 5 091-5 150 MHz is also allocated on a co-primary basis to the fixed-satellite service (Earth-to-space) in accordance with provision **S5.444A** and limited to feeder links for non-geostationary mobile-satellite. Resolution 114(**WRC-95**) mentions that this subject should be reviewed at WRC-01.

Studies showed that sharing between RNSS (space-to-Earth) and MLS or FSS feeder links is not feasible.

Advantages

- Ionospheric delay would be reduced by a factor of ten, allowing higher accuracy of navigation without auxiliary means. Natural and man-made interference would be reduced at the higher frequencies, in addition to which the smaller size of receiver antenna would make practicable the realization of active phased-array antennas capable of rejecting interfering signals, for safety-critical users.
- These directive antennas will also suppress multipath signals that are detrimental to the ranging process.
- Furthermore, the availability of a wider bandwidth able to accommodate a higher-rate code would both increase accuracy and improve the suppression on unmodulated or narrow-band interference.

Disadvantages

- The wavelength decreases at the higher frequency of 5 000 MHz, so this requires the transmission of some 10 dB more power than at 1 600 MHz, if receiving antenna gains are assumed to be the same.

- RNSS (space-to-Earth) unwanted emissions require careful control in order to protect the RAS band below 5 000 MHz, however, filters already exist which can accommodate these requirements.
- RNSS (space-to-Earth) unwanted emissions must meet the aggregate pfd level at the Earth's surface of -124.5 dB(W/m^2) in a 150 kHz band, as specified by ICAO in order to protect MLS operations in the 5 030-5 150 MHz band.

The following four options (3.1 to 3.4) are mutually exclusive. The advantages and disadvantages mentioned above for the band 5 010-5 150 MHz are applicable to the four options below.

Method 3.1

5 010-5 030 MHz

Advantage

The band 5 010-5 030 MHz is lightly used and is not planned for use by the international standard MLS systems.

Disadvantages

- 20 MHz may not be wide enough to accommodate the RNSS requirement. Therefore appropriate technical, but more complex solutions for RNSS (space-to-Earth) systems may be required.
- The separation between RNSS (space-to-Earth) and the radio astronomy service would be a minimum of 10 MHz to protect the radio astronomy service inside its allocation. This may cause difficulties due to the radio astronomy receiver sensitivity outside the band allocated to the radio astronomy service.

Method 3.2

5 010-5 034 MHz

Advantages

- The band 5 010-5 030 MHz is lightly used and is not planned for use by the international standard MLS system.
- RNSS (space-to-Earth) would be provided with sufficient spectrum.

Disadvantages

- The implementation of MLS in the band 5 030-5 034 MHz might preclude the availability of this band for RNSS (space-to-Earth).
- The RNSS (space-to-Earth) transmission would be inside the bandwidth of the front end filter of existing MLS receivers.
- If the band 5 030-5 034 MHz is used for RNSS (space-to-Earth), this could influence the MLS spectrum requirements in the band 5 091-5 150 MHz, which is investigated under Resolution 114(**WRC-95**).
- The loss of assignable MLS channels would have a negative operational impact on other aeronautical radionavigation systems due to channel pairing with DME.

- The separation between RNSS (space-to-Earth) and the radio astronomy service would be the minimum of 10 MHz to protect the radio astronomy service inside its allocation. This may cause difficulties due to the radio astronomy receiver sensitivity outside the band allocated to the radio astronomy service.

Method 3.3

5 066-5 090 MHz (this method implies that MLS is shifted from the band 5 030-5 091 MHz to the band between 5 000 and 5 066 MHz)

Advantages

- RNSS (space-to-Earth) would be provided with sufficient spectrum.
- The radio astronomy allocation immediately below 5 GHz is protected by a separation of 66 MHz from the proposed RNSS (space-to-Earth) allocation.
- By extending the tuning range of the international standard MLS system down to 5 000 MHz, if this is feasible, the total number of available channels remains unchanged.

Disadvantages

- The tuning range for the international standard MLS system needs to be extended down to 5 000 MHz. The feasibility of this frequency shift and the change of pairing with DME has not been studied in ITU-R.
- The necessary frequency and geographical separation between MLS and stations operating in the radio astronomy service needs careful consideration.
- The already installed MLS equipments will need to be replaced (similar to the situation if the band 5 091-5 150 MHz is used for MLS extension but without the associated operational benefits to aviation).

Method 3.4

5 091-5 115 MHz (this method implies that FSS feeder links need to vacate the band)

Advantages

- RNSS (space-to-Earth) would be provided with sufficient spectrum without constraining the use of MLS in the band 5 030-5 091 MHz.
- The RAS immediately below 5 000 MHz would be protected by a separation of 91 MHz from the proposed RNSS (space-to-Earth) allocation.

Disadvantages

- The use of the band 5 091-5 115 MHz by RNSS (space-to-Earth) would be constrained by existing and future use of the non-GSO MSS feeder links or MLS depending on the outcome of Resolution 114(**WRC-95**).
- As sharing between RNSS (space-to-Earth) and FSS (Earth-to-space) is not feasible (see 2.4.1.1.3 c), MSS feeder links would require the allocation of other immediately adjacent frequency bands to satisfy spectrum requirements.

- An existing non-GSO-GMPCS system using the band 5 091-5 250 MHz for two years would be forced to stop transmission in service link beams if RNSS (space-to-Earth) started to operate. The provision of services would be impeded due to the impossibility of modifying the feeder-link frequency plan on board the satellites.
- If the non-GSO-MSS feeder links need to vacate the band 5 091-5 115 MHz this would constrain the use by non-GSO-MSS feeder links in the band 5 115-5 250 MHz (under the assumption that concentration in this band is possible).
- The use of the band 5 091-5 115 MHz by RNSS (space-to-Earth) could result in unacceptable interference to spacecraft feeder-link receivers operating in the band 5 115-5 250 MHz.

2.4.1.3.2 RNSS (Earth-to-space)

Method 1

1 300-1 350 MHz

Advantages

- Taking into account the decoupling of at least 50 dB for low elevation angles on the radiobeacon antenna, studies have shown that a separation distance of no more than 60 km is required to protect ground-based radars. Because of the small number of beacons, sharing of this band with ARNS would not pose undue constraints to RNSS (Earth-to-space).
- Furthermore the low frequency makes it easy to use a single hemispherical coverage antenna at each radiobeacon earth station.

Disadvantage

The necessity of taking into account the above-mentioned separation distance.

Method 2

5 000-5 030 MHz

Advantage

This band is lightly used and is not planned for use by the international standard MLS. It is then very valuable for a system whose aim is to promote safety for RNSS users. The nearby RAS band below 5 000 MHz can also be well protected through the implementation of a separation distance between the beacons and the RAS sites.

Disadvantages

- The higher frequency will require a higher transmission power from the terrestrial beacons.
- In order to protect the MLS, separation requirements from airports using or planning to use MLS will be needed as mentioned above.

2.4.1.4 Regulatory and procedural considerations

If Method 1 and/or Method 2 and/or Method 3, including the options presented under each method, above are adopted the following regulatory changes need to be considered.

RNSS (space-to-Earth)

Allocate to RNSS (space-to-Earth), either 1 164-1 188 MHz, or a portion of 1 151-1 215 MHz, that could allow the operation of multiple RNSS systems, while providing protection to the aeronautical radionavigation service. Priority should be given to ARNS over RNSS, in order to satisfy current and future requirements of the aeronautical radionavigation service. It is recommended that ITU-R develops one or more Recommendations on the technical requirements of RNSS to ensure the compatibility between RNSS and ARNS.

Allocate to RNSS (space-to-Earth) 1 260-1 300 MHz on the same basis as the band below 1 260 MHz while taking into account the operation of spaceborne synthetic aperture radars in the upper band within 1 215-1 300 MHz of the amateur-satellite service in the band 1 260-1 270 MHz and wind profilers in the 1 270-1 295 MHz band.

Allocate a portion of 5 010-5 150 MHz to RNSS (space-to-Earth) while providing protection and replacement spectrum for aeronautical safety services and accommodation of feeder links operating in the FSS. Priority should be given to the aeronautical radionavigation service and the FSS. Measures should be taken to ensure the operation of existing systems up to the end of their lifetimes.

RNSS (Earth-to-space)

Allocate the band 1 300-1 350 MHz, and add a provision to the effect that the use of this band by RNSS earth stations should not cause harmful interference to and not constrain the development of this band by radars.

Allocate a portion of the band 5 000-5 030 MHz, depending on the downlink allocation because the up- and downlink should not be shared.

****

2.4.2 Agenda item 1.15.2

"to consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the 1 215-1 260 MHz and 1 559-1 610 MHz frequency bands"

2.4.2.1 Summary of technical and operational studies

RNSS systems such as GPS and GLONASS are primarily being used in the space-to-Earth direction to provide service to terrestrial users. These systems are, however, also increasingly being used in the space-space direction by spaceborne users for such applications as spacecraft three-dimensional positioning and velocity determination; three-axis attitude control; precise time synchronization; precision orbit determination; and atmospheric science.

The use of RNSS signals is presently protected only through a space-to-Earth allocation in the 1 215-1 260 MHz and 1 559-1 610 MHz bands. Considering current and future operational usage of spaceborne RNSS receivers for scientific and commercial applications, it is important to add the space-to-space direction to the existing RNSS allocations.

Interference studies have been conducted to assess the sensitivity of spaceborne RNSS receivers to interference from RLS, EESS (active), SRS (active), FS, MS and ARNS in the 1 215-1 260 MHz band; from the ARNS and FS in the 1 559-1 610 MHz band; and also their sensitivity to intra-service interference between RNSS systems in these two bands. To assist in the interference studies draft new Recommendation ITU-R M.[8/85] provides technical characteristics of current and prospective RNSS spaceborne receivers. As noted in the draft new Recommendation ITU-R M.[8/85], the characteristics of spaceborne RNSS receivers are different due to differing performance requirements and operational environments.

Potential interference from services in adjacent bands was also examined.

2.4.2.2 Analysis of the results of the studies

The addition of a space-to-space direction to the 1 215-1 260 MHz and 1 559-1 610 MHz RNSS bands will not cause any additional interference to other services since it involves no change to the space-to-Earth transmissions.

Over the past seven years, more than 90 GPS receivers have been flown in space by 20 different countries from around the world for a variety of applications and experiments. There have been no identified cases of interference to spaceborne RNSS receivers from the existing space and terrestrial services in the 1 215-1 260 MHz and 1 559-1 610 MHz bands.

Studies provided demonstrate that RNSS spaceborne receivers can operate satisfactorily in the presence of interference caused by systems in other services as well as other RNSS systems.

It has been concluded that:

a) Given the characteristics of the FS, MS, and RLS systems in the two RNSS bands, they will not cause unacceptable interference to the spaceborne RNSS systems. Interference only becomes noticeable when multiple terrestrial emitters simultaneously illuminate the spaceborne receiver. However, because of the narrow beams of these emitters, the probability of simultaneous illumination is very small and even if it did occur, the duration of the interference event would be very short. Also, in the case of interference from radiolocation emitters, RNSS receivers have high immunity to pulsed interference. In addition, most spaceborne receivers will be pointed away from the Earth looking upwards to the navigation satellites which will further mitigate terrestrial interference.

b) Interference from typical spaceborne synthetic aperture radars of the EESS and SRS in the 1 215-1 260 MHz band is not harmful to RNSS spaceborne receivers. Peak signal power levels were calculated in a worst-case geometry (spaceborne receiver in main beam of SAR) and determined to be well below the levels that would cause preamplifier burnout. Furthermore, the pulse duty cycles of typical SARs are low enough (<10%) that even if the receiver is driven into saturation, the receiver can still successfully operate and the impact on performance is negligible.

c) Intra-service interference into receivers of one RNSS system from emitters of other RNSS systems is tolerable. The worst-case examples of emission from the LSATNAV and MSATNAV systems interfering with GPS receivers were analysed. Interference from the proposed low altitude LSATNAV system only becomes significant when the GPS spaceborne receiver is in the main beam of an LSATNAV satellite and in close proximity (less than 25 km) to it. For the medium-Earth orbit MSATNAV satellites the corresponding range is 350 km. Due to the relative motion of satellite the interference will be rare and will not usually last more than a few minutes unless the satellites are in very similar orbits. Because satellites move in predictable orbits, such outages can be accepted. Similarly, interference from the proposed GSO altitude E-NSS-1 system is negligible.

d) RNSS spaceborne receivers of the currently operating and notified RNSS systems will be able to operate satisfactorily in the presence of adjacent band emissions from GSO MSS (space-to-Earth) satellites below 1 559 MHz.

e) Based on the unwanted e.i.r.p. emission limits specified in Recommendation ITU-R M.1343, the aggregate interference from MSS mobile earth stations into spaceborne RNSS receivers in low-Earth and geostationary satellite orbits is negligible, provided the RNSS carrier frequency is below 1 607 MHz.

f) Based on the results of a worst-case analysis that considered the emissions from the MSS (space-to-Earth) system operating in the 1 613.8-1 626.5 MHz band, a distance separation of only 30 km is required to protect RNSS spaceborne receivers in the 1 559-1 610 MHz band. Considering the existing and currently expected deployment of both MSS (space-to-Earth) systems in the 1 613.8-1 626.5 MHz band and RNSS spaceborne receivers, separations of less than 30 km are not expected to occur in practice and hence RNSS spaceborne receivers will be able to operate satisfactorily in the presence of out-of-band emissions from such MSS systems.

2.4.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

Option A:

Propose the addition of the space-to-space direction to the RNSS (space-to-Earth) allocation in the bands 1 215-1 260 MHz and 1 559-1 610 MHz with a provision indicating that no protection should be given to spaceborne RNSS receivers from RNSS systems already operating in these bands or for which complete advance publication information has been received by the Bureau, prior to the end of WRC-2000.

Advantage

This provides protection for spaceborne RNSS receivers operating within existing and planned RNSS systems from interference from any future RNSS system.

Disadvantage

New radionavigation systems would have to demonstrate compatibility with spaceborne RNSS receivers operating within existing and planned RNSS systems.

Option B:

Propose the addition of the space-to-space direction to the RNSS (space-to-Earth) allocation in the bands 1 215-1 260 MHz and 1 559-1 610 MHz with provisions indicating that:

No protection should be given to spaceborne RNSS receivers from RNSS systems already operating in these bands or for which complete advance publication information has been received by the Bureau, prior to the end of WRC-2000.

Spaceborne RNSS receivers operating in the 1 559-1 610 MHz band should not request protection from unwanted emissions of stations of the MSS (Earth-to-space) operating in the band 1 610-1 660.5 MHz.

Advantages

- This provides protection for spaceborne RNSS receivers operating within existing and planned RNSS systems from interference from any future RNSS system.
- Stations of the MSS (Earth-to-space) will not be subjected to additional constraints due to RNSS (space-to-space) operations.

Disadvantage

New RNSS systems would have to demonstrate compatibility with spaceborne RNSS receivers operating within existing and planned RNSS systems.

Option C:

Propose the addition of the space-to-space direction to the RNSS (space-to-Earth) allocation in the bands 1 215-1 260 MHz and 1 559-1 610 MHz with provisions indicating that:

No protection should be given to spaceborne RNSS receivers from RNSS systems already operating in these bands or for which complete advance publication information has been received by the Bureau, prior to the end of WRC-2000.

Spaceborne RNSS receivers operating in the 1 559-1 610 MHz band should not request protection from unwanted emissions of stations of the MSS (Earth-to-space) operating in the 1 610-1 660.5 MHz band.

Spaceborne RNSS receivers should be deployed and operated such as to avoid or accept possible interference at levels equivalent to those caused by MSS (space-to-Earth) systems in the bands 1 525-1 559 MHz and which are already operating or for which a request for coordination has been received by the BR, prior to the end of WRC-2000.

NOTE - Further studies would be needed to define the level of unwanted emissions from MSS (space-to-Earth) systems - referred to above - into spaceborne RNSS receivers.

Advantages

- This provides protection for spaceborne radionavigation receivers operating within existing and planned RNSS systems from interference from any future RNSS system.
- Stations of the MSS (Earth-to-space) will not be subjected to additional constraints due to RNSS (space-to-space) operations.
- Stations of the MSS (space-to-Earth) - referred to above - will not be subjected to additional constraints due to RNSS (space-to-space) operations.

Disadvantage

New RNSS would have to demonstrate compatibility with spaceborne RNSS receivers operating within existing and planned RNSS systems.

2.4.2.4 Regulatory and procedural considerations

If any of the above Options are adopted the appropriate consequential amendments to Article **S5** would need to be considered for the bands 1 559-1 610 MHz and 1 215-1 260 MHz.

****

2.4.3 Agenda item 1.15.3

"to consider the status of allocations to services other than the radionavigation-satellite (Nos. **S5.355** and **S5.359**) in the 1 559-1 610 MHz band"

Nos. **S5.355** and **S5.359** are applicable. No. **S5.355** allocates the bands 1 540-1 645.5 MHz and 1 646.5-1 660 MHz also to the fixed service on a secondary basis in twenty-five countries. No. **S5.359** allocates the bands 1 550-1 645.5 MHz and 1 646.5-1 660 MHz also to the fixed service on a primary basis in forty-four countries.

2.4.3.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

Relevant Recommendations ITU-R: M.1088, M.1317, M.1318, F.759 and M.[RNSS.CHAR]

Four analyses have been carried out by the ITU-R which considered the potential interference from FS transmitters into the GPS, GLONASS and E-NSS-1. One analysis used the characteristics of FS systems found in Recommendation ITU-R F.759. The other analyses used characteristics of typical FS systems known to be operating in the 1 559-1 610 MHz band.

2.4.3.2 Analysis of the results of studies

The analyses showed that harmful co-frequency interference would be suffered by all RNSS receivers in the main beam of the FS transmitter antenna up to around 50 km for land-based receivers and up to around 400 km or more for aeronautical receivers. On the basis of these studies, it is concluded that RNSS receivers would be unable to support co-frequency interference from FS transmissions within radio line-of-sight. Moreover one analysis showed that typical FS transmitters in the band 1 559-1 592 MHz would cause interference to GPS/Space-Based Augmentation Systems (SBAS) airborne receivers out to the radio horizon. Another analysis showed that a removal of some typical FS transmitters from the band 1 592-1 610 MHz would sufficiently protect GLONASS receivers at a distance greater than 1 km.

It is noted that FS stations registered in the ITU MIFR with higher power and greater bandwidths were not considered in the current studies.

The potential for interference from aeronautical radionavigation (ARNS) pseudolites on RNSS has also been analysed by the ITU-R. The result of this analysis is contained in § 2.2.1.2.5 a).

2.4.3.3 Methods to satisfy the agenda item and their advantages and disadvantages

The RNSS is extensively used today and is undergoing rapid expansion of all its uses including aeronautical and marine safety-of-life navigation. As a result, use by the FS of the band 1 559-1 610 MHz is not recommended.

2.4.3.4 Regulatory and procedural considerations

In order to protect present and future RNSS applications, sharing of the band 1 559-1 610 MHz between RNSS and FS is not recommended.

CHAPTER 3

Non-GSO FSS issues

(WRC-2000 agenda item 1.13 (1.13.1, 1.13.2))

CONTENTS

Non-GSO FSS issues

Agenda item 1.13

"on the basis of the results of the studies in accordance with Resolutions **130 (WRC-97)**, **131 (WRC-97)** and **538 (WRC-97)**"

3.1.1 Agenda item 1.13.1

"to review and, if appropriate, revise the power limits appearing in Articles **S21** and **S22** in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services"

3.1.1 Sharing among non-GSO FSS systems

3.1.1.1 Results of studies relating to sharing between non-GSO FSS systems

Several studies contributed to ITU-R addressed the determination of the number of non-GSO FSS systems that can share co-frequency in the 14/11 and 30/20 GHz bands included in Resolution **130 (WRC-97)**. These studies have shown the following:

– that there are several mitigation techniques that should be considered for use to achieve satisfactory sharing between co-frequency, codirectional non-GSO FSS satellite networks in Resolution **130 (WRC-97)** frequency bands as shown in draft new Recommendation ITU-R S.[Doc. 4/65];

– that non-GSO FSS systems that operate with homogeneity in power flux-density levels at the Earth's surface are able to coexist with much smaller inter-system interference levels in the downlink direction for a given avoidance angle than systems with disparate power flux-densities. Thus, these systems should be able to coexist with a smaller avoidance angle to satisfy downlink requirements;

– that an important factor to be taken into account in the determination of the number of non-GSO FSS systems that can share with each other is potentially acceptable levels of interference along with the corresponding avoidance angles necessary to achieve the required interference objectives (draft revision to Recommendation ITU-R S.1323 [Doc. 4/69] gives guidance for determining interference criteria for non-GSO FSS systems);

– that sharing appears to be difficult for non-GSO FSS systems if they are required to operate with large avoidance angles (around 10° to 15°) in order to share with other non-GSO FSS systems due to the reduction in capacity and the potential increase in outages or coverage degradation;

– that some non-GSO FSS systems may be able to use smaller avoidance angles (about 3° to 7°) to share with other non-GSO FSS systems, thus resulting in an increase in the number of systems that can share a given frequency band.

a) Sharing between homogeneous constellations

The possibility of sharing between non-GSO FSS networks employing homogeneous orbital planes, (i.e., where the altitude and inclination angles of the orbital planes of two or more constellations are almost identical) was studied, and three methods identified to allow such sharing:

– plane interleaving or constellation shift, where a non-GSO constellation has its satellite orbital planes placed in between those of the other constellations;

- satellite interleaving within planes; and
- a combination of the above.

Studies have suggested that, in principle, a rather larger number of homogeneous non-GSO FSS systems may be able to share frequencies with each other than with inhomogeneous constellations, since, if all such systems employed the same orbit height and inclination, and either their respective orbit planes were interleaved or the true anomalies of their respective satellites were interleaved within the same orbit planes, no "in-line" transitions would occur between them. However, considerable cooperation between the various operators would be needed throughout the lifetime of the systems, and simulations have confirmed that even very minor differences between the heights or inclinations of the systems would create the need for some satellite diversity. It is concluded that filings by different operators for non-GSO FSS systems with this degree of similarity are extremely unlikely to occur.

b) Sharing between inhomogeneous constellations

The issue of sharing in the bands 10-15 GHz and 20/30 GHz between non-GSO FSS systems using dissimilar constellation parameters (inhomogeneous systems) was also studied in detail. Simulations have shown that sharing between two inhomogeneous non-GSO FSS systems is feasible if one or both of the systems employs mitigation techniques, including satellite diversity to avoid main beam-to-main beam coupling of interference to and from the other system during "in-line" transitions.

These studies showed that when avoidance angles are required to be impracticably large, other mitigation techniques might be required to allow multiple inhomogeneous non-GSO FSS systems to share the same frequency band. It was also demonstrated that as the number of systems sharing the same frequency band increases, the complexity of satellite avoidance implementation increases. Studies showed that the shortest-term interference into a non-GSO FSS system from multiple non-GSO FSS systems is dominated by a single system and so is not additive in either time and power.

Coordination under No. **S9.12** effectively places the obligation for implementing mitigation techniques, such as diversity on the later of the two systems to be filed with the BR. A subsequently filed third non-GSO FSS system would be faced with implementing mitigation techniques with respect to the earlier two systems, and a fourth with respect to the first three, and so on. Each earth station in a system operating with satellite diversity must be able to "see" an alternative satellite in its constellation whenever an "in-line" transition involving it approaches, and that alternative satellite must have a beam and transponder capacity "free" at the appropriate time, otherwise the link will suffer an outage. Unless such outages can be tolerated by the service being provided, it follows that systems operating diversity require either more satellites, or higher capacity satellites, or both, than systems either not operating diversity or operating diversity with respect to fewer prior systems. In certain situations, depending on the particular characteristics of the systems concerned, the simulations have shown that the requirement for space-sector hardware increased rapidly as a consequence of this factor for non-GSO FSS systems having to exercise diversity with respect to more than two or three other systems.

c) Sharing between high-altitude non-GSO (quasi-GSO) and non-GSO systems

No conclusions were reached regarding sharing between high-altitude non-GSOs (i.e. quasi-GSOs) and lower-altitude non-GSOs, such as LEOs and MEOs. It has been noted that the large difference in orbital characteristics may impose constraints, which need to be assessed through future study by the ITU-R.

d) Maximum effective number of non-GSO FSS system able to share the same frequency band

It was therefore concluded, on the basis of studies performed, that only a small number of constellations using homogeneous orbits and homogeneous transmission parameters could share the same frequency band, but that this sharing could likely be accomplished without the use of interference mitigation techniques, except possibly for earth stations at a certain latitude. It was also concluded that sharing between non-GSO systems employing different orbital characteristics would necessitate some form of interference mitigation to reduce the interference levels and that in this case, the difficulty in mitigating interference increases as the number of systems sharing the band increases.

Studies were also performed to determine the manner in which interference from multiple non-GSO FSS systems aggregates into a GSO FSS earth station. These studies resulted in a method to convert any equivalent power flux-density, $EPFD_{down}$ versus %-of-time curve required to protect GSO downlinks from the aggregate interference from multiple non-GSO FSS systems to the corresponding $EPFD_{down}$ versus %-of-time curve for interference from a single non-GSO FSS system.

These studies also showed that the aggregate interference into a GSO network from "N" non-GSO FSS systems sharing a frequency band will likely be different from the interference into a GSO network caused by one non-GSO FSS system multiplied by a factor of "N" (in either power level or time percentage) since the impact of each non-GSO FSS system will not be identical.

It was agreed that an equivalent number "$N_{effective}$" of systems should be considered for the purposes of studying the impact of aggregate interference from multiple non-GSO FSS systems, under the assumption that each system operates at the single entry EPFD limits.

For the reasons explained above, the use of inhomogeneous parameters was assumed.

The implementation of interference mitigation techniques between the different non-GSO FSS systems in order to provide adequate protection to all other non-GSO systems was considered simultaneously with those mitigation techniques required to meet the single-entry EPFD levels in order to assess the cumulative interference effect from multiple non-GSO FSS systems.

Several studies were reviewed dealing with the determination of the number of simultaneous entries to be considered for determining EPFD levels used in bands covered by Resolution **130 (WRC-97)**, and with sharing among non-GSO FSS systems.

3.1.1.2 Summary

Taking account of the studies leading to assessments of the maximum number of non-GSO FSS systems which are likely to be able to share frequencies, a value of 3.5 for $N_{effective}$ was agreed to be used in the ITU-R studies to determine the final values of single-entry $EPFD_{down}$ versus percentage of time to be applied in bands currently covered under Resolution **130 (WRC-97)**. This value was to be used solely for the purpose of deriving single-entry EPFD masks from aggregate EPFD masks and is not a representation of the actual number of non-GSO FSS systems that can share a given frequency band.

3.1.1.3 Regulatory and procedural considerations

3.1.1.3.1 Coordination between non-GSO FSS systems

It would be beneficial, in order to facilitate sharing between non-GSO FSS systems in the frequency bands covered by Resolutions **130 (WRC-97)** and **538 (WRC-97)**, that the ITU-R should develop a methodology to be used in applying the relevant coordination procedure (No. **S9.12**). Revision of Recommendation ITU-R S.1323 contains several methodologies to derive the permissible level of interference into a wanted non-GSO FSS system, whether the interference is caused by a GSO or by a non-GSO system (See also § 3.1.2.2.2). This permissible level however, relates to the aggregate interference caused by all non-GSO FSS and GSO FSS systems. It is therefore necessary to apportion this aggregate interference into single entry permissible levels to be met by non-GSO FSS systems, taking into account the mechanisms by which all the interference sources cumulate. The ITU-R is continuing its studies to develop such a method.

The Radiocommunication Bureau should not be asked to use the method described in the above paragraph to determine the need for coordination. However, such a method would be very desirable to carry out coordination under No. **S9.12** in a satisfactory way. With the addition of such a method, the coordination process under No. **S9.12** would be facilitated since it would be based on a generally agreed and sufficiently specific method and would therefore facilitate agreement and the timely notification and bringing into service of the non-GSO system for which coordination is sought.

3.1.1.3.2 Example resolution concerning the aggregate EPFD limit from multiple non-GSO systems being exceeded

There is a need to provide a regulatory mechanism that would ensure protection of GSO FSS and GSO BSS networks from the maximum aggregate equivalent power flux-density produced by multiple non-GSO FSS systems in frequency bands where equivalent power flux-density (EPFD) limits have been adopted. One possible mechanism for meeting this objective is a WRC-2000 Resolution that would take the form of the example draft Resolution (Example Resolution WWW) that is included in Annex 2.

3.1.2 Sharing between non-GSO FSS and GSO FSS systems in the bands 10.7-11.7 GHz, 11.7-12.2 GHz (Region 2), 12.2-12.5 GHz (Region 3), 12.5-12.7 GHz (Regions 1 and 3), 12.7-12.75 GHz, 12.75-13.25 GHz, 13.75-14.5 GHz, 17.8-18.6 GHz, 19.7-20.2 GHz, 27.5-28.6 GHz and 29.5-30.0 GHz

3.1.2.1 Protection of the GSO FSS systems

Resolution **130 (WRC-97)** introduced provisional $EPFD_{down}$ and aggregate power flux-density, APFD (which is re-defined as $EPFD_{up}$) limits for non-GSO FSS systems in certain bands intended to protect GSO FSS systems operating co-frequency and requested ITU-R to conduct the appropriate technical, operational and regulatory studies to review the regulatory conditions relating to the coexistence of non-GSO and GSO systems in the FSS.

In order to adequately protect GSO FSS networks, an aggregate interference level from all non-GSO FSS systems, which individually meet the Table **S22-1** limits, needs to be defined. This issue is discussed in § 3.1.1.3.2 and Resolution WWW.

ITU-R has agreed that several mitigation techniques are available to reduce potential interference from non-GSO systems into GSO FSS systems. These techniques may be considered by non-GSO systems in order to operate within the EPFD masks.

3.1.2.1.1 Characteristics of the GSO FSS

Circular Letters CR/92 and CR/116 invited administrations to supply data on existing and planned GSO FSS links in certain frequency bands. The parameters for over 600 14/11 GHz and approximately 200 30/20 GHz carriers were collected in a database. Descriptions of GSO FSS systems are contained in Recommendation ITU-R S.1328. In addition to traditional 14/11 GHz and 30/20 GHz fixed margin FSS systems, i.e. systems that use power to compensate for rain fade, the database and Recommendation ITU-R S.1328 includes a 30/20 GHz GSO FSS system employing adaptive coding to compensate for rain fade.

For fixed margin systems, the more sensitive links include those operating with larger earth station antennas, low link noise temperature, in low rain regions (which could include some links in rain zones A to E), and/or at high altitudes with little or no excess margin. Excess margin is margin above what a link needs to meet its short-term performance objective due to rain.

It was agreed that it is not possible to determine the proportion of sensitive links in the environments based on the information contained in the CR92/CR116 database. However, it is reasonable to suppose that a large number of the links operated or planned to be operated would be less sensitive to short-term interference than the links in the database.

In the revision to Recommendation ITU-R S.1323 [Doc. 4/69], it was agreed that the system designer and operator should have control over the overall performance of a network and have the capability to provide the required quality of service. An additional link margin above that necessary to compensate for fading, e.g. to compensate for equipment ageing, should not be used for the protection from interference by other networks.

The 30/20 GHz GSO FSS system employing adaptive coding provides link robustness to rain fades on a per link basis. The excess margin concept does not apply to adaptive coding systems. Adaptive coding systems set aside a per cent of each beam's channel capacity in reserve as "spare capacity" (similar to rain margin in fixed margin systems) that is used to transmit additional bits/s for links requiring "heavy coding" to compensate for rain. This capacity is sized to cope with the expected rain statistics for a specified availability on a per beam basis which allows constant user data throughput on a link-by-link basis, depending on the link conditions at each user terminal.

For the characteristics of the GSO earth station reference antenna pattern for calculating $EPFD_{down}$ limits, and for conducting interference assessments to GSO networks from non-GSO FSS systems, ITU-R agreed to adopt reference patterns specified in Recommendation ITU-R S.[Doc. 4/57]. These reference antenna patterns are defined in two dimensions only, but it was decided that they would be considered as applicable throughout all rotational planes. Reference patterns were defined to cover both co- and cross-polar signals. These reference patterns differ from those currently referenced in the definitions of $EPFD_{down}$ in Article **S22**, which are based upon worst-case peak envelope patterns. The new agreed reference patterns take into account a more accurate, though conservative, description of the shape of the pattern so that it can be used more realistically in interference calculations involving non-GSO FSS systems, and lead to lower levels of $EPFD_{down}$ than those calculated using the patterns currently referenced in Article **S22**.

Circular Letter CR/115 requested Administrations to provide information on the number, locations and principal characteristics of their current and planned earth station antennas having a receive gain greater than 60 dBi, in order to assess the scope and specifics of a coordination procedure. Several administrations and sector members responded to CR/115, providing data at varying levels of detail on approximately 400 large antennas. Most of the large GSO earth station antennas identified in response to CR/115 are in the 14/11 GHz band. There were few large antennas identified in response to CR/115 in the 30/20 GHz band. Some carriers operating in the band 12.2-12.75 GHz use 18 m antennas with a gain of 65 dBi and other carriers operating in the 17.8-21.2 GHz use 20 m antennas with a gain of 70 dBi.

It was concluded that an additional regulatory procedure would be necessary to protect very large GSO FSS antennas from downlink interference from non-GSO networks. The detailed requirements for this proposed new procedure are given in § 3.1.2.4.

3.1.2.1.2 Protection criteria

a) Description of $EPFD_{up}$, $EPFD_{down}$, $EPFD_{is}$

For the protection of GSO uplinks WRC-97 set provisional limits on non-GSO FSS interference in the form of single validation power limits to be met for 100% of the time. It is recommended that this principle should be retained, but that the limits should be redefined to take into account the discrimination of the receive antenna pattern of the GSO satellite, and termed $EPFD_{up}$ limits.

Recognizing that in certain bands covered by Resolution **130 (WRC-97)** there are allocations to FSS space-to-Earth links and also to either BSS or FSS Earth-to-space links, it is recommended that additional power limits be applied to emissions from non-GSO FSS constellations in those bands in order to protect the receivers of satellites operating in the GSO. These additional limits may be termed $EPFD_{is}$ limits.

For the protection of GSO downlinks it is recommended that the individual limits provisionally adopted by WRC-97 to be met for various percentages of time should be replaced by curves prescribing the power levels not to be exceeded for percentages of time from 0% to 100%, and termed $EPFD_{down}$ masks.

In order to simplify the RR and facilitate the understanding of the provision of Article **S22**, it is recommended that the same generic mathematical definition should be used for the $EPFD_{down}$, the $EPFD_{up}$ and the $EPFD_{is}$. The reference GSO FSS space station antenna patterns in the calculation of $EPFD_{up}$ and $EPFD_{is}$ values should be the single-feed patterns defined in Recommendation ITU-R S.672; for this purpose, in the 11/14 GHz bands a peak gain of 32.4 dBi, a beamwidth of 4° and a first side lobe level of -20 dB should be assumed; in the 20/30 GHz bands a peak gain of 40.7 dBi, a beamwidth of 1.55° and a first side lobe level of -10 dB should be assumed. Annex 1 contains regulatory text that is considered to reflect the agreed changes.

The purpose of the limits contained in Section II of Article **S22** is to give an upper bound to the interference that GSO networks may receive from non-GSO FSS networks in some frequency bands. By analogy with the relevant existing ITU-R S-series Recommendations, a 40 kHz reference bandwidth for the 10-15 GHz bands and reference bandwidths of 40 kHz and 1 MHz for the 17-30 GHz bands should be used when expressing the power limits to be included in Section II of Article **S22**.

b) Time allowances for non-GSO FSS interference

With the exception of links using adaptive coding, the principal criterion used as the basis for the derivation of the validation power limits is that the aggregate interference from all non-GSO FSS systems sharing frequencies with a GSO link should not be responsible for more than 10% of the proportion of time for which the link C/(N+I) ratio is permitted to fall below the shortest-term performance threshold defined for the considered link. This criterion is defined in Recommendation ITU-R S.1323 [Doc. 4/69].

c) Criteria for defining loss of synchronization

An additional criterion identified in Recommendation ITU-R S.1323 [Doc. 4/69] refers to the protection of GSO FSS links from loss of synchronization (sync-loss). Specifically, *recommends* 3.2 stipulates that interference from non-GSO FSS systems shall not lead to sync-loss in the GSO FSS network more than once per "x" days ("x" has not been defined in Recommendation ITU-R S.1323). Sync-loss is related to the level of interference, earth station hardware performance, satellite link margin and rainy events, and sun outages in some cases. Based on measurements for sync-loss thresholds for systems with data rates less than 34 Mbits/s, the ITU-R agreed that the following sync-loss thresholds need to be considered when determining EPFD levels that should not be exceeded:

Modulation and coding	C/(N+I) (dB)
QPSK rate 7/8	6.0
QPSK rate 3/4	5.3
QPSK rate 1/2	3.5
8-PSK	8.1
16-QAM	11.0

In all other cases, and in particular when performance objectives are specified with values lower than those assumed above, the ITU-R agreed to assume a 1 dB degradation from the lowest performance objective to the synchronization loss level.

GSO FSS operators design their links so that sync-loss is a rare event. Rain attenuation is the main cause of unpredictable sync-loss events, and thus earth stations in dry climates can be less prone to sync-loss due to precipitation than most earth stations. However, carriers received by earth stations in dry climates may operate with small threshold margins and hence be more prone than others to sync-loss caused by non-GSO interference. For a typical link a mean-time-between-sync-losses due to non-GSO interference of less than about eight weeks would not be acceptable to most GSO FSS operators. The time required to verify compliance with a target of this order makes it impracticable for mean-time-between-sync-losses to be imposed as a regulatory requirement; however the sync-loss interval may be used in the determination of "operational" limits and in the development of a methodology for checking whether they are met. In making use of a sync-loss interval the effect of orbit perturbations and imperfect station keeping should be taken into account.

The degree of protection against sync-loss due to non-GSO interference peaks is related to rain rate. For the same sync-loss threshold C/(N+I) the $EPFD_{down}$ corresponding to the interfering signal (I) can be much lower in the driest areas than in the wettest areas for the same link availability.

d) Criteria for systems using adaptive coding

Recommendation ITU-R S.1323 [Doc. 4/69] also addresses the protection criteria for GSO FSS systems employing adaptive coding. Adaptive coding systems are planned in the 30/20 GHz band but not in the 14/11 GHz band. This criterion defines the impact from all non-GSO FSS systems on a per beam basis versus a per link basis for fixed link margin systems. It allows the aggregate interference from non-GSO systems to be responsible for a 10% decrease in the amount of spare capacity available to adaptive coding links that require heavy coding.

At the 14/11 GHz band frequencies, it was agreed that no additional protection measures should be considered for the protection of GSO systems employing adaptive coding, over and above the protection measures required for other GSO systems.

e) Protection of GSO links having very large earth station antennas

Some links with very large earth station antennas may not be adequately protected by the $EPFD_{down}$ limits proposed in Annex 1. The following points were agreed regarding GSO FSS networks having earth stations with very large antennas:

- Transmissions to earth stations with very large antennas need to be protected, and thus it may be desirable that they be treated separately. A coordination procedure would be one possible mechanism to ensure this protection.
- Downlink transmissions to very large GSO earth station antennas are most sensitive to interference. This sensitivity is more related to the availability degradation than to the potential for synchronization loss (i.e. the 100% $EPFD_{down}$ value).
- For very large GSO earth station antennas, the following factors would facilitate achieving mutually satisfactory coordination:
  - Non-GSO interference $EPFD_{down}$ levels at or near the maximum are likely to occur over only a small proportion of the Earth's surface.
  - The locations of interference $EPFD_{down}$ levels at or near the maximum are likely to differ from one non-GSO system to another.
- Coordination would be triggered for GSO FSS networks having very large earth station antennas meeting all of the following conditions:
  - Earth station antenna maximum isotropic gain (APS4/C.10 *c)* 2)) of 64 dBi or higher for the band 10.7-12.75 GHz and 68 dBi or higher for the bands 17.8-18.6 GHz and 19.7-20.2 GHz, which corresponds to approximately 18 metres.
  - G/T_l of 44 dB/K or higher, where G is earth station antenna maximum isotropic gain and T_l (APS4/C.10 *c)* 5)) is the lowest total system receiving noise temperature which includes the earth station noise temperature, retransmitted uplink noise, cross-polarization noise, inter-modulation noise, and any other internal link noise sources. The link noise temperature as defined herein excludes external noise sources.
  - Space station emission bandwidth (APS4/C.7 *a)*) of 250 MHz or higher for the band 10.7-12.75 GHz and 800 MHz or higher for the bands 17.8-18.6 GHz and 19.7-20.2 GHz.
- In addition to the conditions indicated in the preceding point, the coordination trigger should contain the condition of the $EPFD_{down}$ level radiated by the non-GSO FSS system into the earth station employing the very large antenna considered when this earth station is pointed to the wanted GSO satellite. Two $EPFD_{down}$ values in each band would be needed and exceeding either $EPFD_{down}$ would trigger coordination. Coordination would be triggered if the $EPFD_{down}$ exceeds:
  - either –174.5 dB(W/(m^2.40 kHz)) for any percentage of time or [x] dB(W/(m^2.40 kHz)) for [y]% of the time in the frequency band 10.7-12.75 GHz;
  - either –151 dB(W/(m^2.MHz)) for any percentage of time or [x'] dB(W/(m^2.MHz)) for [y']% of the time in the frequency bands 17.8-18.6 GHz and 19.7-20.2 GHz.

  These $EPFD_{down}$ threshold criteria would be sufficiently conservative to trigger coordination. A reference to these $EPFD_{down}$ thresholds is needed in Appendix **S5**.

- Based on the responses to CR/115, setting the threshold size of very large GSO earth station antennas at 64 dBi in the band 10.7-12.75 GHz and 68 dBi for the bands 17.8-18.6 GHz and 19.7-20.2 GHz clearly indicates that there would be few cases requiring coordination.
- Additional regulatory and procedural conditions (e.g. due diligence provisions) may be needed to reduce the number of cases requiring coordination.
- The conditions required to initiate coordination would be that the notifying administration provide the specific earth station location (APS4/C.10 *b)*) and satellite location (APS4/C.10 *a)*) and that the BR check that all conditions required to initiate coordination are met.

Implementation of this coordination procedure may include additions or modifications to Articles **S9** and **S22** and Appendixes **S4** and **S5**. Annex 3 contains example regulatory and procedural text for coordination between non-GSO FSS transmitting space stations and GSO receive earth stations with very large antennas. Since there is no mandatory requirement to provide specific earth station information associated with GSO FSS networks, specific provisions would be needed to grandfather existing or planned earth stations having very large antennas. Additional guidance would need to be added to the *Instructions for Filling Out the Form of Notice APS4/II and APS4/III Relating to Space Radiocommunication Stations* distributed via CR/65.

3.1.2.1.3 Methodologies used to assess the adequacy of the limits to protect GSO FSS

a) Methodologies and treatment of the CR/116 links

The ITU-R agreed that in deriving candidate EPFD limits, different methodologies can be used (e.g. Recommendation ITU-R S.1323 [Doc. 4/63]), and then using procedure D included in Annex 2 of Recommendation ITU-R S.1323 [Doc. 4/63] to verify compliance with the requirement that the interference from all non-GSO systems should not account for more than 10% of the short-term time allowance and refine the candidate masks. These methodologies do not apply to 20/30 GHz GSO FSS systems employing adaptive coding.

In order to apply the 10% criterion to carriers in the CR/116 database, it was agreed that the following treatment should be given to links where the time percentage of unavailability without non-GSO interference (T_f) is not equal to 90% of the time percentage T_t corresponding to the unavailability target (fading plus interference): the total allowable unavailability time percentage (with non-GSO interference) should be ($T_f + T_t/10$). Note that when T_f is less than 90% of unavailability target, the link has excess margin; when T_f is more than 90% of unavailability target, the link has insufficient margin.

b) Methodologies to derive the single-entry EPFD$_{down}$ mask from the aggregate EPFD$_{down}$ mask

The 10% of unavailability time allowance criterion leads to the derivation of aggregate EPFD limits. A method was needed to derive a single-entry mask from each aggregate mask.

It was agreed that the following method be employed to convert any EPFD$_{down}$ versus %-of-time curve required to protect GSO downlinks, having earth station antennas of approximately 10 m and larger in the 10.7-12.75 GHz band and 5 m and larger in the 17.8-18.6 GHz and 19.7-20.2 GHz bands, from the aggregate interference from $N_{effective}$ (equal to 3.5: see § 3.1.1.1 c)) non-GSO FSS systems, to the corresponding curve for interference from a single non-GSO FSS system:

The aggregate mask is drawn using a linear abscissa scale for the EPFD in decibel units increasing to the right, and a logarithmic scale for percentage of time increasing upwards. A second line is then drawn, 10 log($N_{effective}$) dB to the left of the first line, thus representing power division. A third line is then drawn, dividing the first line by a factor of $N_{effective}$, thus representing time division. The single-entry mask is then formed by taking the second line from 100%-of-time to the point where it crosses the third line, the third line between that point and the point where the third line reaches 0.01%-of-time, and the first (i.e. aggregate) line for percentages of time below 0.001%. The single-entry mask is completed by drawing a straight line between the 0.01%-of-time EPFD and the 0.001%-of-time EPFD.

For smaller earth station antennas the third line is taken for all percentages of time less than the point where it crosses the second line.

In those cases where the time-shifted and the power-shifted curves do not intersect, the following procedure is applied:

1) a point P greater than or equal to the 1% of time on the aggregate curve is selected;
2) the corresponding point P on the time-shifted and the corresponding point P on the power-shifted are connected;
3) the single entry curve consists of the power-shifted portion for time between 100% and P%, the segment created in 2) for the time between P% and (P/ $N_{effective}$)% and the time-shifted segment for times less than (P/ $N_{effective}$)%;
4) using the derived single entry mask, the reverse procedure is applied to derive a new aggregate mask. The new aggregate mask is then verified to ensure that it is not greater than the original aggregate mask. If this condition is not met, a new point P is chosen and steps 2) and 3) are repeated.

c) Development of continuous EPFD curves

Once the final limits have been determined by WRC-2000, a new Recommendation if practicable will be developed by ITU-R to provide continuous curves of equivalent power flux-densities versus percentage time for a range of antenna diameters of the GSO FSS earth station to be protected, in order for designers of satellite networks to know that the protection will be adequate in the case of antennas of sizes other than those at which the Radiocommunication Bureau will check compliance.

3.1.2.1.4 Results of studies relating to the review/revision of the provisional power limits appearing in Section II of Article S22

a) $EPFD_{up}$ and $EPFD_{is}$

ITU-R agreed on single-entry $EPFD_{up}$ and $EPFD_{is}$ limits in the 14/11 GHz and 30/20 GHz bands with associated reference antenna beamwidth and radiation pattern: see Annex 1.

It was also concluded that there would be a need to include $EPFD_{up}$ limits in Article **S22** to protect GSO BSS feeder links in the band 18.1-18.4 GHz, if WRC-2000 decides that this band may be used by non-GSO FSS Earth-to-space other than BSS feeder links. The level considered appropriate for these limits to protect GSO BSS feeder links is that proposed in Annex 1 for the $EPFD_{up}$ limits in the adjacent band (17.8-18.1 GHz) and for $EPFD_{is}$ limits in the 18.1-18.4 GHz band. Other sharing considerations in this band are given in § 3.2.

b) $EPFD_{down}$

ITU-R agreed on single-entry $EPFD_{down}$ limits specified in tabular form. The limit consists of the curve on a plot which is linear in decibels for the EPFD levels and logarithmic for the time percentages and defined linear segments joining the data points.

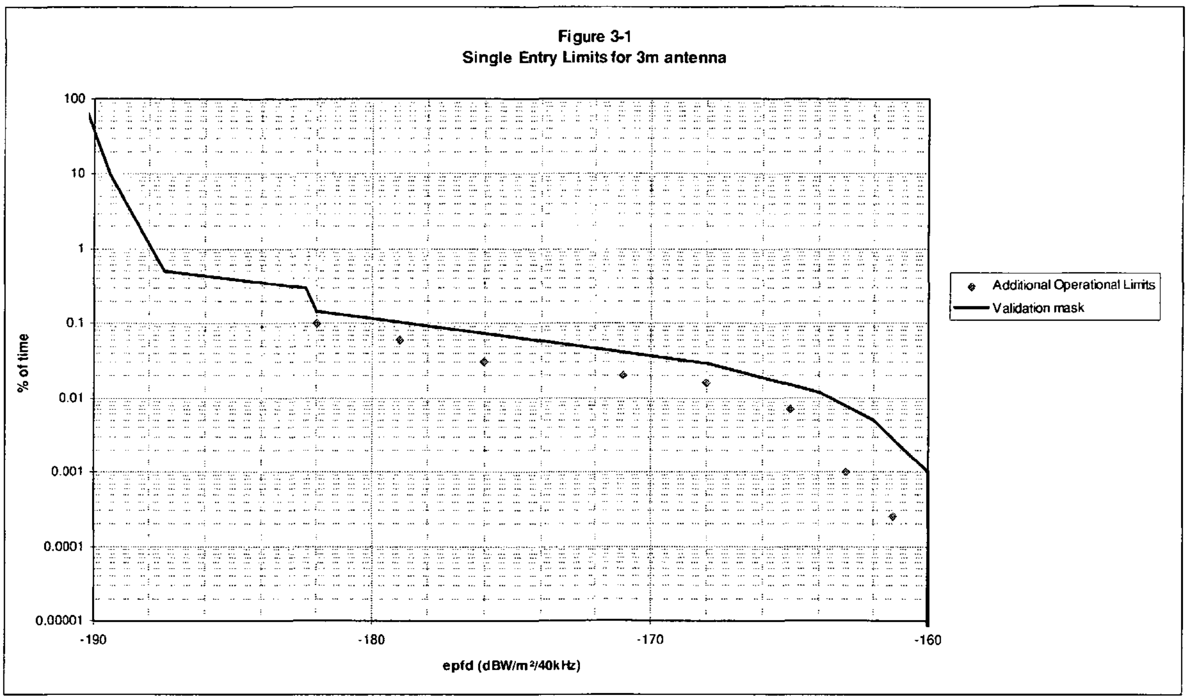
c) **$EPFD_{down}$ for 10.7-12.75 GHz band**

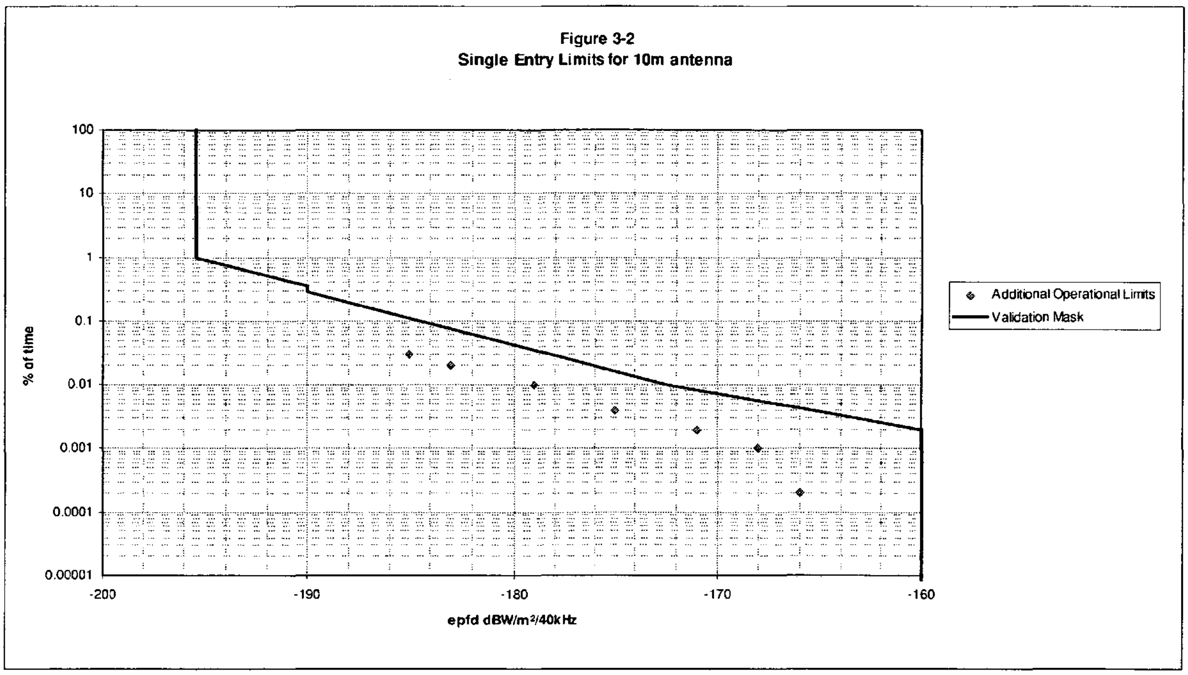
Although the 10% criterion of Recommendation ITU-R S.1323 was not met in all cases for the validation limits given in Annexes 1 and 2, an agreement by CPM-99 on $EPFD_{down}$ limits in the band 10.7-12.75 GHz was reached. This agreement was based on the following compromise, involving i) "validation" $EPFD_{down}$ masks for reference GSO earth station antenna diameters of 60 cm, 1.2 m, 3 m and 10 m; ii) "operational" $EPFD_{down}$ limits for all antenna diameters between 3 m and 18 m; iii) "additional operational" $EPFD_{down}$ limits for antenna diameters of 3 m and 10 m; and iv) EPFD validation limits for antenna diameters exceeding 60 cm located at high latitudes.

Compliance with the validation masks will be checked by BR under **S11.31**, using software conforming to the specification described in § 3.1.5.1. The administrations represented at CPM-99 agreed to support the adoption and approval of an ITU-R Recommendation which contains that specification. The CPM agreed on single-entry validation masks that, in conjunction with operational EPFD limits, adequately protect GSO FSS systems using 60 cm, 1.2 m, 3 m and 10 m antenna diameters. These masks are given in Table **S22-1** of Annex 1.

Additionally, during operation the non-GSO system shall be subject to the provisions of § 3.1.2.4.7 in order to ensure protection of GSO earth stations using antennas of diameter ≥3 m against loss of demodulator synchronization. The operational limits defined in § 3.1.2.4.7 are given in Table **S22-4** of Annex 1 for certain antenna diameters. For antenna diameters between the tabulated values, the limits are given by linear interpolation using a linear scale for $EPFD_{down}$ in decibels and a logarithmic scale for antenna diameter in metres.

Also, the administration proposing the non-GSO system shall commit that, when in service, the interference from that system into any operational antenna of diameter of 3 m will meet the additional operational limits given in Table **S22-4A1** of Annex 1, and that the interference into any operational antenna of diameter of 10 m will meet the additional operational limits given in Table **S22-4A2** of Annex 1. To assist administrations in making such commitments, ITU-R proposes that WRC-2000 should adopt a Resolution requesting ITU-R to develop, as a matter of urgency, a new or revised Recommendation containing a methodology to determine the cumulative time distribution of the actual $EPFD_{down}$ levels radiated by a non-GSO FSS system into a GSO FSS earth station antenna. The methodology should include means of evaluating the interference into intermediate antenna diameters. For illustration purposes, Figure 3-1 shows the "validation" $EPFD_{down}$ mask and the "operational" $EPFD_{down}$ limits for antenna diameters of 3 m. Similarly, Figure 3-2 provides a graphical representation for the 10 m antenna.





d) EPFD$_{down}$ for 17.8-18.6 GHz

ITU-R agreed on single-entry EPFD$_{down}$ validation limits in conjunction with operational limits that adequately protect GSO FSS systems operating in the 17.8-18.6 GHz band using 1 m, 2 m, and 5 m antenna diameters. These limits are given in Annex 1.

e) **EPFD$_{down}$ for 19.7-20.2 GHz**

ITU-R agreed on single-entry EPFD$_{down}$ validation limits in conjunction with operational limits that adequately protect GSO FSS systems operating in the 19.7-20.2 GHz band using 70 cm, 90 cm, 2.5 m and 5 m antenna diameters. These limits are given in Annex 1.

3.1.2.2 Protection of non-GSO FSS systems

3.1.2.2.1 Characteristics of the non-GSO FSS

In Circular Letter CR/102 (30 July 1999), administrations were invited to supply data on their planned non-GSO FSS links under a format enabling the assessment of the impact of interference to and from non-GSO systems. The technical characteristics of a number of proposed non-GSO FSS systems have been received and compiled in Recommendation ITU-R S.1328. These parameters have been used and will be available in the sharing studies among GSO and non-GSO systems.

3.1.2.2.2 Protection criteria

The protection criteria included in the draft revision of Recommendation ITU-R S.1323 [Doc. 4/69] apply to the protection of both GSO and non-GSO systems from interference caused by either GSO or non-GSO FSS systems. The same criteria as indicated in § 3.1.2.1.2 for the protection of GSO FSS systems from interference caused by non-GSO FSS systems have therefore been considered in the reverse direction, i.e. for the protection of non-GSO FSS systems.

In-line interference leading to synchronization loss in a non-GSO FSS system can only occur under very specific geometric situations related to the characteristics of both the wanted non-GSO FSS system and interfering GSO networks.

3.1.2.2.3 Methodologies used to assess the adequacy of the limits to protect non-GSO FSS

For geostationary networks, the link to be protected is defined between a given GSO earth station and a given GSO space station. Both of them being fixed, the slant range, elevation and rain attenuation distribution model are static. For the protection of non-GSO systems, the situation is different since the link to be protected is between one given non-GSO earth station and the selected satellite in the non-GSO constellation. This means that the physical link path is constantly moving. The elevation, the slant range and the rain attenuation distribution are not constant anymore. The path attenuation parameters vary with time.

In order to take this dynamic nature into account, a methodology has been developed and is included in § 5 of Annex 1 and Annex 3 of Recommendation ITU-R S.1323 [Doc. 4/69], and has been used to assess the impact of GSO FSS or GSO BSS interference on both regenerative and transparent non-GSO FSS satellite systems, with respect to the two protection criteria in Recommendation ITU-R S.1323 [Doc. 4/69], as reported in § 3.1.2.2.2 above.

The application of this methodology requires some assumptions on the scenarios likely to characterize the aggregate interference environment created by all GSO FSS or GSO BSS networks, in particular on the average orbital spacing between GSO FSS or GSO BSS networks serving the same area or areas adjacent to that served by the wanted non-GSO FSS system. Assumptions are also required on the geographic distribution of the earth stations in these networks. Realistic assumptions also need to be taken concerning the maximum pfd level radiated by the GSO FSS or GSO BSS space stations. On the basis of a representative scenario, it was found that the non-GSO systems would be sufficiently protected at the level of the criteria mentioned in § 3.1.2.2.2 if the off-axis e.i.r.p. density levels proposed in § 3.1.2.2.4 were to be adopted as limits to be included in

Article **S22**. However it does not necessarily follow that less stringent off-axis e.i.r.p. density levels would not adequately protect the non-GSO FSS systems.

3.1.2.2.4 Results of studies relating to the off-axis e.i.r.p. density limits

Section VI of Article **S22** contains off-axis e.i.r.p. density limits, which have been suspended, for GSO and non-GSO FSS earth stations operating in the frequency bands 12.75-13.25 GHz and 13.75-14.50 GHz. Review of these limits has resulted in the following considerations if they were to be included in the Radio Regulations:

- the values in Section VI could be increased by 3 dB while still providing protection to the non-GSO FSS systems from earth stations operated with GSO FSS satellites;
- such limits should impose a minimum of constraints on existing and future GSO networks, knowing that GSO earth stations would then have to meet a regulatory requirement, which is not the case at present;
- in particular, special attention should be given to existing earth stations or earth stations planned to be operated in the near future together with TT&C transmissions;
- it was agreed that the inclusion in the RR of FSS earth station off-axis e.i.r.p. density limits in all the plane orientations with regard to the GSO, should not lead to a situation where the GSO operators would have to provide information on the typical performance of their earth stations in more than two orthogonal planes.

Recommendation ITU-R S.524 [Doc. 4/66] provides maximum permissible levels of off-axis e.i.r.p. density from GSO FSS earth stations in the frequency bands 12.75-13.25 GHz and 13.75-14.50 GHz with these levels applying within ±3° of the GSO arc. Some existing or future GSO FSS earth stations may exhibit off-axis e.i.r.p. density levels higher than those specified in Recommendation ITU-R S.524 [Doc. 4/66] in directions beyond ±3° of the geostationary arc due to off-set feeds and spillover effects. In recognition of this characteristic it was agreed that the off-axis e.i.r.p. density levels for GSO earth stations at angles greater than 3° from the GSO should reflect a 3 dB relaxation relative to the levels which are currently recommended in Recommendation ITU-R S.524 [Doc. 4/66] within 3° of the GSO arc.

Regarding the off-axis e.i.r.p. density limits for GSO FSS earth stations operating in the frequency bands 12.75-13.25 GHz and 13.75-14.50 GHz included in No. **S22.26** and currently suspended, these levels have been reviewed for GSO FSS earth stations and agreed for communication links as follows. It has to be noted that these levels are 3 dB higher than those defined in Recommendation ITU-R S.524 [Doc. 4/66].

Off-axis angle	Maximum e.i.r.p. density	
$3° \leq \varphi \leq 7°$	$42-25 \log\varphi$	dB(W/40 kHz)
$7° < \varphi \leq 9.2°$	21	dB(W/40 kHz)
$9.2° < \varphi \leq 48°$	$45-25 \log\varphi$	dB(W/40 kHz)
$48° < \varphi \leq 180°$	3	dB(W/40 kHz)

For FM-TV emissions with energy dispersal, the limits above may be exceeded by up to 3 dB provided that the off-axis total e.i.r.p. of the transmitted FM-TV carrier does not exceed the following values:

Off-axis angle	Maximum e.i.r.p.	
$3° \leq \varphi \leq 7°$	56-25 logφ	dBW
$7° < \varphi \leq 9.2°$	35	dBW
$9.2° < \varphi \leq 48°$	59-25 logφ	dBW
$48° < \varphi \leq 180°$	17	dBW

For FM-TV carriers, which operate without energy dispersal, should be modulated at all times with programme material or appropriate test patterns. In this case, the total off-axis e.i.r.p. of the emitted FM-TV carrier shall not exceed the following values:

Off-axis angle	Maximum e.i.r.p.	
$3° \leq \varphi \leq 7°$	56-25 logφ	dBW
$7° < \varphi \leq 9.2°$	35	dBW
$9.2° < \varphi \leq 48°$	59-25 logφ	dBW
$48° < \varphi \leq 180°$	17	dBW

If limits were to be included in Section VI of Article **S22**, the following would apply to the Telecommand and Ranging carriers:

- Telecommand and ranging carriers transmitted to geostationary satellites would be allowed to exceed the limits by up to 16 dB when used in the normal mode of operation of the satellite (i.e. earth station transmitting telecommand and ranging carriers to a directive receiving antenna on the space station).
- In other modes of operation of the GSO satellite, telecommand and ranging carriers would be exempted from the limits.

With regard to provisions for grandfathering of existing earth stations, these should be developed such that the levels defined above are not applied to earth station antennas which have been brought into operation at any time and have been operating with a satellite network in the fixed-satellite service for which complete coordination or notification information has been received before 2 June 2000. Additionally, provisions should also ensure that any subsequent operation of earth stations put into operation before the specified date, to other satellite networks in the FSS, does not result in greater levels of off axis e.i.r.p. than those resulting from the previous operation to the above-mentioned network.

As an alternative to the inclusion of limits in Section VI of Article **S22,** two options have been identified:

– One would be the suppression of Section VI of Article **S22.** However, administrations may be encouraged to use applicable ITU-R Recommendations. Thus no FSS earth station off-axis e.i.r.p. density limits would be included in the Radio Regulations. This would have the advantage of imposing no additional technical or regulatory constraints on GSO FSS earth stations. On the other hand, this would not provide protection for GSO and non-GSO networks, in particular since Recommendation ITU-R S.524 is applicable only within 3° of the GSO arc in the 14 GHz band. It would not provide clear guidelines to non-GSO system designers, thus not ease sharing of spectrum between users.

– The second would consist in incorporating by reference in Section VI of Article **S22** the maximum permissible e.i.r.p. values contained in Recommendation ITU-R S.524, as appropriately modified.

3.1.2.2.5 Off-axis e.i.r.p. density limits applicable to GSO FSS earth stations operating in the frequency band 27.5-30.0 GHz

ITU-R studies to date have been carried out only for the band 29.5-30.0 GHz and in the context of GSO/GSO sharing. The results are reflected in the revision of Recommendation ITU-R S.524 [Doc. 4/66] in *recommends* 4 and the associated notes. No off-axis e.i.r.p. masks have yet been developed for the case of GSO FSS earth stations operating in the frequency range 27.5-29.5 GHz for which work is ongoing.

In *considering further h),* Resolution **130 (WRC-97)** states that non-GSO FSS systems have been proposed in some of these bands which could meet these limits and would not require specific protection from existing and future GSO FSS systems, provided that minimum constraints are applied to GSO FSS systems, such as off-axis earth station e.i.r.p. limits.

ITU-R has developed Recommendation ITU-R S.524 [Doc. 4/66] which recommends off-axis e.i.r.p. levels. This Recommendation was based on studies between GSO systems. These levels may also be used to form the basis for providing guidance to non-GSO system designers.

In order not to constrain the development of GSO systems and also to provide the necessary guidance to non-GSO system designers, the following off-axis e.i.r.p. limits may be included in the Radio Regulations, if it is considered appropriate by WRC-2000:

Off-axis angle	Maximum e.i.r.p. density	
$3° \leq \varphi \leq 7°$	28-25 logφ	dB(W/40 kHz)
$7° < \varphi \leq 9.2°$	7	dB(W/40 kHz)
$9.2° < \varphi \leq 48°$	31-25 logφ	dB(W/40 kHz)
$48° < \varphi \leq 180°$	-1	dB(W/40 kHz)

These limits apply to earth stations operating with networks in the GSO FSS in the frequency band 29.5-30.0 GHz and should apply for any angle φ in any direction outside 3° of the GSO arc.

The *Notes* 14 to 22 found in the revision of Recommendation ITU-R S.524 [Doc. 4/66] should be read in conjunction with the above.

It is noted that these values are 6 dB higher than the corresponding values in Recommendation ITU-R S.524 [Doc. 4/66], and that the impact of these higher values on non-GSO FSS systems has not been studied.

The same alternatives to inclusions of limits in Section VI of Article **S22** as identified at the end of § 3.1.2.2.4 would also apply in the 29.5-30 GHz band.

3.1.2.2.6 Off-axis e.i.r.p. density limits applicable to non-GSO FSS earth stations

The view was expressed that having some off-axis e.i.r.p. density limits applied to non-GSO earth stations would help the sharing between non-GSO networks. It was proposed that, in the bands 12.75-13.25 GHz, 13.75-14.5 GHz, 27.5-28.6 GHz and 29.5-30.0 GHz, the levels that would apply to earth stations operating with GSO would also apply to earth stations operating with non-GSO.

To date there have been no technical studies on the need for establishing off-axis e.i.r.p. limits applicable to non-GSO FSS earth stations. There was agreement that the only possible reason for establishing such limits would be to facilitate sharing between non-GSO FSS systems. The view was expressed that if such limits are applied to the earth stations of a given non-GSO network, they would possibly be helpful only in decreasing the amount of interference affecting its own satellites (internal interference) and not in facilitating sharing between non-GSO FSS systems. Further study is needed to confirm these points prior to WRC-2000. In addition, all technical studies conducted by the ITU-R apply only to GSO FSS earth stations, as clearly indicated by the scope of Recommendation ITU-R S.524 [Doc. 4/66], which summarizes the work performed to date by the ITU-R on this topic.

Sharing in the non-GSO environment depends on a wide variety of factors (e.g. orbits and number of satellites in each constellation, hand-over strategies, in-line avoidance techniques, and traffic patterns). Therefore, there is a need to study the whole interference environment before concluding whether any potential benefit of establishing limits would justify constraining, possibly unnecessarily, non-GSO FSS systems. Moreover, in some cases having off-axis limits would in fact make sharing between non-GSO FSS systems more difficult, because it would prevent the introduction of link balancing, which has been recognized as an efficient mitigation technique to promote sharing (see draft new Recommendation ITU-R S.[Doc. 4/65]).

Therefore, no consensus could be reached on whether off-axis e.i.r.p. should be established for earth stations transmitting to non-GSO satellites. Further studies are required on this issue.

3.1.2.3 Feasibility of the limits and constraints on the development of the systems and services involved

3.1.2.3.1 $EPFD_{up}$ and $EPFD_{is}$ Limits

No significant problems are foreseen, either for non-GSO FSS systems to meet the proposed $EPFD_{up}$ and $EPFD_{is}$ limits, or for GSO FSS systems to be adequately protected by them.

3.1.2.3.2 $EPFD_{down}$ Limit Masks

a) Introduction

The results of studies reported in § 3.1.2 of this Report enabled the CPM to reach the following conclusions as to the appropriate power limits to be placed on non-GSO FSS systems, in order to provide the desired protection to GSO FSS and GSO BSS networks without causing undue constraints to any of the systems and services sharing these frequency bands.

b) Consequences for GSO Systems

The introduction of power limits into Article **S22**, to share frequencies with non-GSO FSS systems, represents the acceptance of a burden on the part of the GSO FSS networks: i.e. the establishment now of acceptable interference levels from non-GSO FSS systems into all present and future GSO FSS networks, and the quantification of the protection provided for GSO FSS under No. **S22.2** in the relevant bands.

In order to ensure protection of GSO systems, a number of worst-case circumstances have been assumed in drawing up the specification for the BR compliance verification software. The $EPFD_{down}$ mask used to calculate the impact of non-GSO downlink emissions on each link in the CR92/CR116 database is based on a combination of conservative assumptions which for individual links has a low probability of occurring.

Taking into account the fact that the above assumptions have had to be made, attention is drawn to the following factors:

- The ITU-R analyses were conducted with the aim of protecting as many of the CR92/CR116 links as possible.
- The $EPFD_{down}$ limits must be met for every location on the Earth's surface and for any pointing direction towards the GSO. However, under normal circumstances, some non-GSO FSS constellations will generate their maximum $EPFD_{down}$ level in only a modest proportion of the Earth's surface. Computer simulations have shown that due to orbit perturbations, these non-GSO FSS constellations may generate their maximum $EPFD_{down}$ levels over a larger proportion of the Earth's surface, but this will result in fewer interference events in any given location. For each earth station location the maximum interference peaks will be relatively infrequent. Also, $EPFD_{down}$ levels below the maximum may be a problem for some GSO links. Quantification of these factors depends heavily on the characteristics of the non-GSO FSS system.
- ITU-R antenna reference patterns, including the pattern in draft new Recommendation ITU-R S.[Doc. 4/57], are employed for GSO earth stations, in both the ITU-R analyses and the BR software specification. These reference patterns necessarily err on the side of caution, and in practice the roll-off of the GSO earth station antenna main beam is likely to be rather faster than modelled. Also, in the models of non-GSO satellite antennas used in the analyses, the side-lobe gain assumed is likely to be somewhat higher than reality. These factors lead to conservative estimates of the durations and levels of interference peaks.
- The methodologies used to derive EPFD masks lead to conservative results because the only sources of short-term degradation taken into account are rain fading and non-GSO interference. It is noted that the rain fade models used are long-term averages, and that the rain attenuation varies substantially from year to year.
- The EPFD limits have to be met by the non-GSO system on a worldwide/GSO arc basis. The resulting EPFD mask is an envelope of all possible worst-case situations and each EPFD distribution produced by the examination software must be within the EPFD limit mask. The EPFD distribution of any single non-GSO system will therefore not follow exactly the EPFD limit mask.
- With the use of orbital avoidance, the highest $EPFD_{down}$ levels are expected to be caused by the non-GSO satellite antenna side lobes. Non-GSO systems typically use phased array antennas. Side-lobe levels for these antennas vary over the anticipated life of the non-GSO satellite due to element failures and phase and amplitude errors. These errors tend to increase satellite side lobes and change their pointing directions. It is expected that the parameters used to generate the pfd/e.i.r.p. mask correspond to the performance of the non-GSO satellite over its anticipated lifetime.
- The simulation methodology developed by ITU-R, for verification of compliance with Article **S22** of the EPFD levels produced by a non-GSO FSS system, involves the generation of a power flux-density mask (pfd mask) which corresponds to the envelope of the power radiated by each non-GSO space station, independently of the resource allocation scheme used by the non-GSO system, and independently of the traffic carried by the non-GSO system. In particular land masses and oceans are assumed to be served with maximum traffic capability at each time step of the simulation. This pfd mask is then used by the software to calculate the EPFD radiated into a given GSO earth station, by assuming, at each time step, that all the satellites contributing to interference operate at this maximum pfd level. Although this approach may be appropriate, although still conservative, to calculate the worst-case EPFD

level that may be generated at the worst-case location of the Earth, it results in an overestimation of the statistical distribution of the EPFD levels at a given point of the Earth. This also highlights that the overall impact of the interference at the GSO system level will also be overestimated as all the earth stations of a given GSO system will actually experience different EPFD statistics, the upper bound of which is the EPFD mask specified in Article **S22**.

- The methodologies used to derive the pfd masks that are input into the BR compliance examination software use what is by definition a "worst-case" scheduling algorithm for beam pointing. A study has shown that under certain circumstances the curve of EPFD statistics run over a large number of Earth points with a more realistic scheduling algorithm such as pointing in the direction of the cells that result in the highest elevation angle beams, is within 0.3 dB of the worst-case statistics obtained with the worst-case algorithm.

For those individual links which are not fully protected by the $EPFD_{down}$ validation masks, the operational limits and the additional operational limits, various ways of compensating for any shortfall in protection were considered and it was concluded that the most convenient one would usually be an increase in the satellite e.i.r.p. allocated to the GSO link, where feasible. Most of the links in the CR92/CR116 database which the $EPFD_{down}$ limits do not protect according to the 10% criterion or synchronization loss avoidance criterion are characterized by large earth station antennas and small margins.

Employing hard limits without a coordination procedure is a common practice for the FSS in the Radio Regulations in those instances where the cost of the constraints accepted by the services involved are outweighed by the benefit of coexistence without the need for coordination. Studies demonstrate that the provisional $EPFD_{down}$ limits and associated percentages of time for the large dish sizes considered by WRC-97 may not adequately protect their individual GSO FSS links terminating in very large earth station antennas as defined in § 3.1.2.4.4. $EPFD_{down}$ limits and associated percentages of time that would provide sufficient protection to GSO networks having very large earth station antennas would be substantially more stringent than limits that would protect the largest dishes considered at WRC-97. Coordination would provide an alternative sharing arrangement without placing undue constraints on the design of non-GSO systems, although it is noted that it would prove an additional burden on such systems. However, for coordination to be a satisfactory solution for the non-GSO system operators there should be very few cases requiring coordination, and the protection requirements should be clearly defined. Therefore, the thresholds for triggering coordination must be set such that in reality coordination is triggered in very few cases. The ITU-R proposed that coordination should be triggered for GSO FSS networks having very large earth station antennas and meeting a combination of thresholds as described in § 3.1.2.4.4.

c) Consequences for non-GSO Systems

The decision to operate a non-GSO FSS system in bands where $EPFD_{down}$ limits apply is based on balancing the benefits and costs of the associated economic, technical and other considerations of such operation.

The consequences for non-GSO systems of implementing $EPFD_{down}$ limits in a given band must be considered in two parts. First is the impact on the non-GSO system of having to implement satellite diversity to protect GSO systems in general. This burden has been documented in ITU-R (see CPM-97 Report). Second is the relative impact of compliance with $EPFD_{down}$ limits vs. coordination with individual GSO systems. $EPFD_{down}$ limits do provide the benefit to present and future non-GSO systems of avoiding individual negotiations with every GSO system. However, this benefit is granted at the cost of increased constraints imposed on non-GSO FSS systems (to protect GSO FSS networks) that depend on the protectiveness of the power limits adopted. $EPFD_{down}$ limits that are too tight would result in protecting the entire GSO arc to a greater degree than would be necessary if individual coordinations were completed with each GSO system.

The following sections describe the sensitivity of these burdens to variations in the level of the power limits:

– **Lower non-GSO satellite antenna side lobes**

  The use of non-GSO satellite antennas with the best available radiation patterns will lead to the most efficient use of the radio-frequency spectrum. Antenna design can become complex and there are costs associated with developing antennas with low side lobes. Antennas with fixed boresight pointing can normally achieve lower side-lobe levels than electronically-steered antenna beams that require large scan angles.

  Most non-GSO satellites use multiple beams. The aggregate antenna side-lobe level is dependent both on the single beam side-lobe performance and the number of co-frequency active beams. Assuming a given antenna design, aggregate side-lobe improvement will require a reduction in the number of active beams and, consequently, the capacity of the non-GSO system. For example; a 1 dB tightening of the maximum EPFD limit, where non-GSO satellite side lobe into GSO earth station main beam is the highest EPFD case, may reduce the non-GSO system capacity up to 20% if no other measures were used.

  To design the satellite antennas to produce side-lobe levels lower than the current state of technology and meet more stringent short-term EPFD limits may be possible but would lead to a significant increase in complexity, mass and cost due to the larger number of radiating elements and of controllable devices (variable phase shifters, variable power dividers, variable attenuators) per antenna, as well as the consequent increase in the size and number of radiating elements. It would also result in substantially increased program costs, technical risks, and launch costs.

– **Decrease in carrier power levels to meet short-term EPFD limits**

  Decrease in non-GSO satellite carrier power will result in a reduction in capacity (e.g. "1 dB capacity", i.e. 20% reduction in capacity for 1 dB of tightening, in the case of CDMA systems) or will cause a need to increase earth station terminal size that may limit the ability to provide service in certain areas.

– **Modification of waveform to reduce power spectral density**

  In the case of spread signals, this would result in an increase in bandwidth, which could result in decreased capacity and higher production cost. In cases where non-GSO carriers utilize the entire allocated band, reduced power spectral density would be achieved only if additional spectrum was made available.

– **Increase in exclusion angle (GSO arc avoidance)**

  Increase in exclusion angle will either decrease the non-GSO system coverage if the constellation is unchanged, or increase the number of satellites and/or increase the number of beams per satellite in the constellation to maintain coverage.

3.1.2.4 Regulatory and procedural considerations

The existing text in the RR (e.g., those Resolutions **130 (WRC-97)**, **131 (WRC-97)**, and **538 (WRC-97)** (incorporated by reference), and Articles **S5**, **S9**, **S11**, **S21**, **S22**, and Appendices **S4** and **S5**) was reviewed and some possible options were identified for modifications to these provisions.

In reviewing the current regulatory provisions in the current *resolves* contained in Resolutions **130 (WRC-97)**, **131 (WRC-97)**, and **538 (WRC-97)**, possible modifications, suppressions or transfers to Articles in the RR were identified. Examples of possible modifications to Resolutions **130 (WRC-97)** and **538 (WRC-97)** are included in Annex 5 to this Chapter. Possible changes were also identified to Articles **S5**, **S9**, and **S22** and Appendices **S4** and **S5** in order to reflect the results of ITU-R studies. Examples of possible modifications to footnotes in Article **S5** as a result of determinations to be made with regard to Resolutions **130 (WRC-97)** and **538 (WRC-97)** are included in Annex 6 to this Chapter. It is anticipated that revised Resolutions **130 (WRC-97)**, **131 (WRC-97)**, and **538 (WRC-97)**, or other resolutions, will be required i) to cover the transition period of the provisional limits between WRC-97 and WRC-2000 and ii) to implement the revised Article **S22** at the end of WRC-2000. It was also noted that the *instructs the Radiocommunication Bureau* of Resolutions **130 (WRC-97)** and **538 (WRC-97)** states that "as of the end of WRC-99, to review and, if appropriate, revise, any finding previously made on the compliance with the limits contained in Article **S22** of a non-GSO FSS system for which notification information has been received between 22 November 1997 and the end of WRC-99. This review shall be based on the values in Article **S22**, as revised, if appropriate, by WRC-99". A regulatory procedure may be required to implement "this review of the findings".

Additionally, the following were specifically identified as areas that may require possible procedural/regulatory actions:

a) inclined geostationary orbits;

b) very large receive earth station antennas;

c) off-axis e.i.r.p. density;

d) software;

e) operational limits to the $\mathrm{EPFD_{down}}$ by non-GSO systems in certain frequency bands;

f) GSO TT&C (space-to-Earth); and

g) possible misapplication of single-entry limits.

3.1.2.4.1 Article S5

Due to modifications to Resolutions **130 (WRC-97)** and **538 (WRC-97)**, consequential changes will be required to the footnotes in Article **S5** that make reference to these Resolutions. (See Annex 6.)

3.1.2.4.2 Article S22, Section II

Based on the work of ITU-R, there will be a need to revise Article **S22**, Section II. It is noted the tables in Article **S22** contain references to ITU-R Recommendations and, if it is determined that this is not acceptable (incorporation by reference), then an annex to Article **S22** containing the necessary information from the ITU-R documents will be required. Annex 1 provides examples of possible modifications to Article **S22**, Section II.

3.1.2.4.2*bis* Appendix S4, Annex 2A

Based on the work of ITU-R, there will be a need to revise Appendix **S4**, Annex 2A. Annex 9 contains the proposed changes.

3.1.2.4.3 Inclined geostationary orbits

ITU-R agreed that the $EPFD_{down}$ masks adopted for the protection of non-inclined GSO links would also protect links using satellites in slightly inclined orbits up to 2.5º inclination. Operation of GSO links up to 4.5º could be provided by operational limits as in Table **S22-4**. Where the actual orbital inclination of a GSO satellite exceeds 4.5º, some other regulatory procedure would be required.

3.1.2.4.4 Very large receive earth station antennas

§ 3.1.2.1.2 e) states that some very large earth station antennas may not be adequately protected by the $EPFD_{down}$ limits in proposed Annex 1 and a coordination procedure may be necessary. Implementation of this coordination procedure may include additions or modifications to Articles **S9** and **S22** and Appendices **S4** and **S5**. Annex 3 contains example regulatory and procedural text for coordination between non-GSO FSS transmitting space stations and GSO receive earth stations with very large antennas.

3.1.2.4.5 Off-axis e.i.r.p. density

§§ 3.1.2.2.4 to 3.1.2.2.5 of this Report address the results of studies relating to off-axis e.i.r.p. density limits for GSO/FSS earth stations.

Three options were identified for the consideration of off-axis e.i.r.p. issue in the Radio Regulations. Considerations associated with these options are addressed in §§ 3.1.2.2.4 and 3.1.2.2.5.

- **Option 1**

  Suppress the current Section VI of Article **S22** of the Radio Regulations. Thus no FSS earth station off-axis e.i.r.p. limits would be included in the Radio Regulations.

- **Option 2**

  Include FSS earth station off-axis e.i.r.p. limits in Section VI of Article **S22** for the following frequency bands: 12.75-13.25 GHz, 13.75-14 GHz, 14-14.5 GHz and 29.5-30.0 GHz.

- **Option 3**

  Incorporate by reference an ITU-R Recommendation, when available. This option would provide a mechanism for updating the off-axis e.i.r.p. values as appropriate.

Annex 7 of this Chapter contains examples of possible modifications to Section VI of Article **S22** that reflects three options above.

3.1.2.4.6 Software

The examination software intended for use by the BR would be used to compute EPFD statistics from a constellation of non-GSO satellites at specific GSO earth station locations. The cumulative probability distribution function (CDF) curves of EPFD for a single non-GSO system produced by the software would then be tested against the EPFD limits in the Radio Regulations for a decision as to whether the non-GSO system satisfied or failed the EPFD limits. It is envisioned that any non-GSO system that did not meet the EPFD limits and associated time percentages would receive an unfavourable finding from the Bureau. Regulatory and procedural work is needed regarding the examination process and results, including the following:

a) procedure for using the software;

b) definition of additional required input information by modification of Appendix **S4** or another method, and Bureau examination of input data for correctness and completeness before the data is used as software input. Administrations would provide BR with only the additional information that is useful to BR to regenerate the pfd/e.i.r.p. mask. Procedural work will be necessary to distinguish between "incorrect or incomplete information" and other changes in the system;

c) a transition plan, including identification of the date by which the required input information must be received from administrations having non-GSO FSS systems for which Appendix **S4** data was previously received by the Bureau and which now must submit new information. Provisions will also be needed to determine whether the new information is within the envelope of the existing Appendix **S4** information and the system would maintain the original date priority;

d) in order to determine the need for coordination under the proposed ADD **S9.7A** and ADD **S9.7B**, the Bureau would determine the $EPFD_{down}$ radiated by the non-GSO FSS system into earth stations employing very large antennas when the antenna is pointed toward the wanted GSO satellite. This examination would be one of the steps in determining the need for coordination. Although this examination is likely to be carried out by the Bureau's software, these results would have no impact on the determination of whether a non-GSO system met the EPFD limits;

e) publication requirements for input and output information;

f) outputs from the software, including basic outputs available to all administrations and detailed outputs that the Bureau could make available on request to the administration submitting the application, for their internal use and/or for use in case of a dispute;

g) procedure to allow administrations having GSO FSS networks the opportunity to comment on the findings of the Bureau under No. **S9.12** within four months after publication. This may include identification of a limited number of GSO earth station locations where it believes that the EPFD limits in Article **S22** are exceeded. The results from these test locations could also be employed when operational EPFD levels are examined;

h) procedures to allow the Bureau and administration concerned to inspect the detailed output.

3.1.2.4.7 Operational limits to the $EPFD_{down}$ by non-GSO systems in certain frequency bands

$EPFD_{down}$ masks have been developed to fulfil the protection criteria defined in Recommendation ITU-R S.1323 [Doc. 4/69]. These masks include limits, not to be exceeded for 100% of the time, which are being referred to below as the "validation limits". Recognizing that the validation limits may not fully protect some links from occasional synchronization loss, it is recommended that the following principles be applied:

i) An additional limit would be imposed on the actual $EPFD_{down}$ produced by a non-GSO FSS system. This "operational limit" is lower than the validation limit ($EPFD_{down}$ for 100% of the time). A non-GSO FSS system would be deemed to have fulfilled its obligations under No. **S22.2** as long as its $EPFD_{down}$ into operational GSO earth stations as defined in § 3.1.2.1.4 never exceeds the operational limit.

ii) The validation limits and operational limit would be included directly in Article **S22**. However the BR/ITU, under **S9.35** and **S11.31**, would verify non-GSO FSS compliance only with the $EPFD_{down}$ masks corresponding to the validation limits.

iii) Should an operating non-GSO FSS system exceed the operational EPFD limit into an operational GSO earth station, all necessary steps to ensure that interference caused to that GSO earth station is restored to levels at or below the operational EPFD limit would have to be taken by the non-GSO network as expeditiously as possible.

iv) The determination of whether a non-GSO FSS system is exceeding the operational EPFD limit would be made by individual administrations and their GSO system operators. A reliable means of measuring the actual interference corresponding to the EPFD produced by a non-GSO FSS system would assist administrations in this regard. This is expected to be developed in ITU-R as a draft new Recommendation prior to WRC-2000.

v) The contents of this section (§ 3.1.2.4.7) would not apply to very large antennas as defined in § 3.1.2.1.2 e). The principles in iii) and iv) above also apply to the additional operational limits in Tables **S22-4A1** and **S22-4A2** in Annex 1.

Therefore, based on the above considerations, the CPM proposes that a maximum "operational" EPFD limit as shown in Table **S22-4** in Annex 1 be included in the Radio Regulations to protect GSO networks against sync-loss.

Additional regulatory work to develop a procedure based on this concept may be needed.

3.1.2.4.8 Additional $EPFD_{down}$ limits to protect GSO FSS in the bands 10.7-11.7 GHz (in all Regions), 11.7-12.2 GHz (Region 2), 12.2-12.5 GHz (Region 3), and 12.5-12.75 GHz (Regions 1 and 3)

With respect to any GSO FSS antenna of 3 or 10 metres that is operational in the above bands, the additional operational $EPFD_{down}$ levels described in § 3.1.2.1.4 were agreed.

These additional limits would be included as limits on non-GSO FSS system operation within Article **S22**. As the limits are operational in nature, it is proposed to include them as additional tables to be considered under Table **S22-4** (see Annex 1). An administration proposing a non-GSO FSS system would have to commit that the proposed system will meet the limits that are described in this section (e.g. through inclusion of a requirement in Appendix **S4**). A method of assessing interference levels for intermediate antenna sizes should also be developed within ITU-R (see § 3.1.2.1.3 c)).

To assist administrations, further study is required within ITU-R to develop a methodology (either in a new Recommendation or a modification to an existing Recommendation) to determine the time distribution of the actual EPFD levels radiated by a non-GSO FSS system into a 3 to 10 metre GSO FSS antenna. It was agreed that a Resolution by WRC-2000 to undertake these studies as a matter of urgency would be appropriate.

ITU-R also agreed that it is essential to develop, as a matter of urgency, Recommendations to permit administrations to check compliance with the operational limits that are described in this section (as well as those operational limits described in § 3.1.2.4.7 above).

3.1.2.4.9 GSO TT&C (space-to-Earth)

The ITU-R agreed that depending on the final $EPFD_{down}$ values, there may be a need to develop provisions to protect GSO TT&C carriers in the space-to-Earth direction.

3.1.2.4.10 Possible misapplication of single-entry limits

The ITU-R identified the desirability of identifying regulatory solutions to the possible misapplication of single-entry limits by dividing a non-GSO system into several smaller non-GSO systems which independently meet the limits. It was agreed that that such misapplication would invalidate the entire basis of the derivation of the single-entry limits.

3.1.3 Sharing between non-GSO FSS and GSO BSS systems in the bands 11.7-12.5 GHz (Region 1), 11.7-12.2 GHz and 12.5-12.75 GHz (Region 3), 12.2-12.7 GHz (Region 2), 17.3-18.1 GHz (Regions 1 and 3) and 17.8-18.1 GHz (Region 2)

3.1.3.1 Protection of GSO BSS systems

Resolution **538 (WRC-97)** introduced provisional EPFD and APFD (which is re-defined as $EPFD_{up}$) limits for non-GSO FSS systems in certain bands intended to protect GSO BSS systems operating co-frequency, and requested ITU-R to conduct the appropriate technical, operational and regulatory studies to review the regulatory conditions relating to the coexistence of non-GSO FSS and GSO BSS systems.

ITU-R developed a draft new Recommendation ITU-R BO.[Doc. 11/138], referred to as BSS draft new Recommendation in the rest of § 3.1.3. This Recommendation addresses protection criteria, contains the BSS links to be protected, and descriptions of methodologies to be used in verifying protection of the BSS. The work was performed under the following principles:

a) that the equivalent power flux-density limits as defined in Article **S22** of the RR and applicable respectively to non-GSO FSS systems to be operated in the 12 GHz bands shared with BSS and in the 17 GHz frequency bands shared with BSS feeder links be derived and specified in such a way:
   - that they satisfy the criteria in *recommends* 1.1 and 1.2 of the above draft new Recommendation when applied to a set of representative GSO BSS and associated feeder-link system characteristics, as provided in Annex 1 to this Recommendation;
   - that the apportionment of the aggregate interference allowance specified in *recommends* 1.1 and 1.2 to derive single entry limits be based on the effective number of non-GSO FSS systems that are anticipated to share the same frequency bands;
   - that these limits are specified by continuous curves of cumulative density function for a range of representative GSO receiving antenna sizes.

3.1.3.1.1 Characteristics of the GSO BSS

In performing the studies requested by Resolution **538 (WRC-97)**, it was clearly impracticable for ITU-R to gather and analyse data on all existing and planned GSO BSS networks using the frequency bands covered by Appendices **S30** and **S30A**. In Circular Letters CR/92 (14 April 1998) and CR/116 (15 February 1999), administrations were therefore invited to supply data on a set of representative GSO BSS links. A number of administrations responded to these letters, ITU-R has assembled those responses received prior to 22 March 1999 into a database of GSO BSS parameters.

This database includes the detailed characteristics of more than 300 BSS links. Bearing in mind that it includes sensitive BSS links with respect to interference from non-GSO FSS systems, it was considered as the appropriate basis to assess the adequacy of the current limits, as well as alternative candidate limits, to ensure protection of GSO BSS links so as not to cause undue constraints on any of the systems involved, and has been used for this purpose.

The complete set of submitted links is contained in Annex 1 of draft new Recommendation ITU-R BO.[Doc. 11/138]. This database of links includes both reference parameter links, operational links and links representing future technologies. They represent links employing both digital modulation techniques and FM analogue modulation techniques. The range of earth station sizes is from 30 cm to 450 cm.

One important BSS characteristic used to calculate $EPFD_{down}$ statistics is the BSS receive antenna pattern. To provide reference patterns for this purpose, ITU-R developed a draft new Recommendation ITU-R BO.[Doc. 11/137]. This Recommendation provides a unified set of reference antenna patterns for all regions. A set of three reference patterns are provided: one for $D/\lambda > 100$, one for $25.5 < D/\lambda \leq 100$, and one for $11 \leq D/\lambda \leq 25.5$. These patterns should be used when determining $EPFD_{down}$ statistics.

3.1.3.1.2 Protection criteria

Recommendation ITU-R BO.[Doc. 11/137] outlines the protection criteria for BSS from non-GSO FSS interference. It is noted that the criteria to protect GSO BSS systems from interference caused by non-GSO FSS systems are similar to those adopted for the protection of GSO FSS systems.

3.1.3.1.3 Methodologies used to assess the adequacy of the limits to protect GSO BSS

As discussed in the previous sections, there are two criteria for the protection of GSO BSS from non-GSO FSS interference.

ITU-R developed two methodologies to determine whether the first criterion, a 10% increase of the BSS link unavailability, was met. These two methodologies are described in detail in Annexes 2 and 3 of draft new Recommendation ITU-R BO.[Doc. 11/138]. *Recommends* 3 of BSS draft new Recommendation establishes that both of these methodologies could be used in assessing the impact on the GSO BSS from non-GSO FSS systems.

ITU-R also developed a methodology for assessing whether the second criterion, loss of video picture continuity, was met. This methodology is described in detail in Annex 4 of draft new Recommendation ITU-R BO.[Doc. 11/138].

In addition, it was agreed to use the method of § 3.1.2.1.3 b) to go from aggregate $EPFD_{down}$ mask to single entry $EPFD_{down}$ mask or vice versa. Since the BSS earth station antenna sizes are less than 10 m, it was decided to restrict this methodology to the power addition zone and the time addition zone.

Consistent with the approach of § 3.1.1.1 d), a value of 3.5 for "$N_{effective}$" was adopted in order to relate the single entry masks to the aggregate masks. It is noted that "$N_{effective}$" is used for computation purposes only and is not a representation of the actual number of non-GSO FSS systems that can share a given frequency band.

3.1.3.1.4 Results of studies relating to the review/revision of the provisional power limits appearing in Section II of Article S22 for the protection of GSO BSS systems subject to Appendix S30 plans and associated feeder links

a) $EPFD_{up}$ and $EPFD_{is}$ limits

The concepts of $EPFD_{up}$ and $EPFD_{is}$ limits were agreed. The first set of limits is to protect the GSO BSS feeder links receive space stations from interference caused by non-GSO FSS transmit earth stations using an Earth-to-space allocation. The second set is to protect the GSO BSS feeder links receive space stations from interference caused by non-GSO FSS space stations using a space-to-Earth allocation.

The agreed single entry $EPFD_{up}$ limit is -160 dB(W/(m^2.40 kHz)). This $EPFD_{up}$ limit applies to the bands 17.3-18.1 GHz (Regions 1 and 3) and 17.8-18.1 GHz (Region 2). It is proposed that, the above-mentioned limit be also applicable to the frequency band 17.3-17.8 GHz (Region 2), in order to protect BSS feeder links in Region 2 from non-GSO FSS uplinks in Regions 1 and 3. With regard to the 17.3-17.8 GHz allocation to non-GSO FSS (uplink) in Region 2 see 3.2.2.

The agreed single entry $EPFD_{is}$ limit is -160 dB(W/(m^2.40 kHz)). This $EPFD_{is}$ limit applies to the bands 17.8-18.1 GHz.

b) $EPFD_{down}$

It was agreed that $EPFD_{down}$ masks specified by continuous curves of cumulative density function, as called by *recommends* 2.3 of the draft new Recommendation ITU-R BO.[Doc. 11/138], would be used rather than masks specified by discrete EPFD points as used in the provisional limits. Such continuous masks, specifying the maximum allowed level of $EPFD_{down}$ as a function of the percentage of time, would provide a more realistic fit to the interference caused by non-GSO FSS systems into GSO BSS systems.

The procedure described in § 3.1.3.1.3 above has been applied on the GSO BSS link included in the database reported in § 3.1.3.1.1 above for the 12 GHz band, in order to assess the compliance of candidate $EPFD_{down}$ limits with the protection criteria considered under § 3.1.3.1.2 above. The limits considered above for $EPFD_{up}$ and/or $EPFD_{is}$, as applicable, were also included in the calculations (aggregate value of -153 dB(W/(m^2.40 kHz)), which took into account the impact of non-GSO FSS interference on the overall GSO BSS links (feeder link + downlink).

Tables in Annexes 1 and 2 provide the $EPFD_{down}$ masks in terms of the allowable single entry and aggregate EPFD levels compatible with an effective number of 3.5 non-GSO FSS interfering systems into the various antenna sizes that may be considered for the receive earth station antenna.

These masks were agreed for all antenna diameters, i.e. 30 cm, 45 cm, 60 cm, 90 cm, 120 cm, 180 cm, 240 cm and 300 cm. This agreement reflects the compromise reached between the parties by not imposing unacceptable constraints on any of them. This agreement is based on the following:

- Validation $EPFD_{down}$ masks for the above BSS earth stations antennas diameter.
- Latitude dependent validation 100% of the time $EPFD_{down}$ limits for 180 cm, 240 cm and 300 cm BSS earth stations antennas.
- Operational 100% of the time single entry $EPFD_{down}$ limits for 240 cm BSS antenna diameters in a certain northern high latitude area of Region 2.

The limit in the third bullet is required because the power of BSS transmissions that can be radiated toward certain northern high latitude area of Region 2 is limited by the existing pfd limits section 5c) of Annex 1 to Appendix **S30**. This leads to the use of larger BSS earth station antennas in this geographical area and more sensitive links. But the protection of a limited area should not impose worldwide constraints on non-GSO FSS. This limit may be implemented during a transition period if the pfd limits in section 5c) of Annex 1 to Appendix **S30** are relaxed, taking into account the lifetime of operational BSS spacecraft and those to be launched in a short term. Information on operational limit is provided in sections 3.1.2.4.7 and 3.1.6.2.

To assist administrations, further study is required within ITU-R to develop a methodology (either in a new Recommendation or a modification to an existing Recommendation) to determine the actual EPFD level radiated by the non-GSO FSS systems into a 240 cm GSO BSS antenna. It was agreed that a Resolution by WRC-2000 to undertake these studies as a matter of urgency would be appropriate.

3.1.3.2 Interference to non-GSO FSS systems from BSS systems

The use by non-GSO FSS systems of the frequency bands subject to Appendices **S30** and **S30A** Plans at 12 and 17 GHz was addressed by WRC-97 (Resolution **538 (WRC-97)**). It should be noted that *considering c)* of Resolution **538 (WRC-97)** states that "non-GSO systems should not be entered into these Plans and therefore should not apply the procedures associated with the Plans and should not be protected by these procedures".

A study presented to WRC-97 (Document CMR-97/62) advised that the interference from Appendices **S30** and **S30A** Plans into non-GSO FSS systems sharing the same bands would be acceptable, assuming that the e.i.r.p. levels of the assignments in the Plan do not exceed the levels of the 1977 and 1983 Plans.

On this basis, the ITU-R, noting that the plan modification process would in practice limit the possibility of exceeding these levels, concluded that there would be no need to introduce specific provisions to protect non-GSO FSS systems from modifications to Appendices **S30** and **S30A** Plans.

Further study on this issue may be required in the future if higher power levels appeared to be necessary in the BSS and BSS feeder links in Appendices **S30** and **S30A** Plans.

Concerning the interference that may be caused into non-GSO FSS uplinks by GSO BSS feeder links in the 17.8-18.1 GHz band in Region 2 and, should WRC-2000 decide an allocation to non-GSO FSS (Earth-to-space) in this band, in the 18.1-18.4 GHz band in all three Regions, it was concluded that off-axis e.i.r.p. limits similar to those considered for the 13.75-14.5 GHz might be appropriate. Further study is required however, to determine the appropriate level for these limits.

3.1.3.3 Regulatory and procedural considerations

There is a need to ensure that the aggregate EPFD produced by all co-frequency non-GSO FSS systems does not exceed the maximum interference levels, as determined by the agreed to aggregate EPFD masks, that are necessary to protect these GSO BSS systems.

Some of the considerations in § 3.1.2.4 (including 3.1.2.4.9) apply also in this case.

3.1.4 Sharing between non-GSO FSS systems and terrestrial and space science services in the bands 10.7-12.75 GHz, 12.75-13.25 GHz, 13.75-14.5 GHz, 17.3-18.4 GHz (Earth-to-space), 17.7-19.3 GHz (space-to-Earth), and 27.5-28.6 GHz

3.1.4.1 Protection of fixed-service systems from interference caused by non-GSO FSS space stations in bands covered by Article S21

3.1.4.1.1 Protection of the fixed service in the 10.7-12.75 GHz band

a) Characteristics of the fixed-service systems in the 10.7-12.75 GHz band

The FS characteristics used for the evaluation of pfd limits for non-GSO FSS satellites in the 10.7-12.75 GHz band are given in the following:

Elevation angles	0 and 0.2°
Antenna height	0 metres
Antenna gain	45 and 49 dBi
Antenna pattern	Recommendation ITU-R F.1245
Latitudes	25, 45 and 60°
Gaseous attenuation	Recommendation ITU-R SF.1395
Feeder loss	3 dB
Polarization loss	Note 7 of Recommendation ITU-R F.1245
Receiver thermal noise	-140 dB(W/MHz)

These characteristics are representative of a majority of links in that frequency range.

b) Fixed service protection criteria in the 10.7-12.75 GHz band

The aggregate FS protection criteria in the 10.7-12.75 GHz range are given as follows in draft new Recommendation ITU-R F.[Doc. 9A/TEMP/65] to be submitted to RA-2000 for approval:

- Maximum I/N = +20 dB
- Long-term interference: D_{ltEPO} or FDP (see Recommendation ITU-R F.1108-2) of 10%, where:

$$D_{ltEPO} = (0.89 \times \int_{10^{-6}}^{1} \frac{I(t)}{N} dt) \times 100\%$$

D_{ltEPO} is the error performance objective degradation due to long-term interference.

I(t)/N is the interference-to-noise ratio that could be exceeded during no more than "t" fraction of any month time.

These aggregate FS interference criteria have been derived from considerations of the allowable degradation of Error Performance Objective (EPO) due to interference from systems operating co-primary, on typical FS links using ATPC features.

c) Methodologies used to assess the adequacy of the limits to protect the fixed service in the 10.7-12.75 GHz band

Many analyses using the pfd mask simulation method have been used for assessing the adequacy of the pfd limits for the protection of the FS. In this method, the statistics of the theoretical aggregate power levels received at an FS station are calculated by applying pfd limits under consideration to each visible satellite of the non-GSO FSS constellation[1].

In the derivation of the pfd limits defined in § 3.1.4.1.1 d), it was determined that if the calculated FDP results exceed the criteria of § 3.1.4.1.1 b) by no more than a few per cent for worst-case geometries, this does not mean that the FS links would actually be impaired. It must be noted that the pfd mask analysis is overly conservative in that it computes interference (both long term and short term) that exceeds what would be produced by an operating non-GSO FSS system. This is

[1] Annex 1 of Recommendation ITU-R F.1108-2 provides guidance on the calculation of visibility statistics of space stations operating in circular non-GSO orbits as seen by a terrestrial station.

because the analysis assumes that all the visible satellites of the non-GSO FSS constellation radiate simultaneously the maximum pfd limit in the direction of the FS system under consideration, which is unrealistic. In addition, such an assumption does not take into account the patterns of real satellite antennas, the power limitation of each satellite or the restrictions that self-interference would impose on a non-GSO FSS system.

Calculations are made assuming that the FS receiver antenna is pointing in the direction of the worst-case azimuth for the non-GSO constellation under consideration, since in that pointing direction, the long-term and short-term power levels generated by the non-GSO constellation into the FS receivers are maximum.

Studies in other bands that have considered a more realistic modelling of a similar problem have produced results providing further evidence supporting that the pfd limits defined in § 3.1.4.1.1 d) are adequate. The method used takes into account some fundamental operational constraints of non-GSO FSS systems by using more realistic downlink models developed to generate pfd distribution profiles for a range of arrival angles which are used in place of the maximum-allowed pfd mask.

Given the methodology and assumptions used for evaluating the pfd limits, it can be assumed that the FS aggregate interference criteria given in draft new Recommendation ITU-R F.[Doc. 9A/TEMP/65], can be applied for each single non-GSO FSS constellation. These conclusions remain valid if the number of co-frequency non-homogeneous non-GSO FSS systems were in the range three to five.

d) Results of studies relating to the review/revision of the power limits appearing in Article S21 in the 10.7-12.75 GHz band

The current Article **S21** per satellite pfd limits, as defined below and as discussed more fully in draft new Recommendation ITU-R SF.[Doc. 4-9S/AI] (submitted to RA-2000 for approval), are adequate for the protection of the FS in the 10.7-12.75 GHz band from aggregate interference from three assumed non-homogeneous, non-GSO FSS systems. Moreover, the contribution of GSO interference to the sharing has been shown as not being significant. Studies support and validate this conclusion. These results would remain valid if the number of non-GSO FSS systems were in the range three to five.

- In the 10.7-11.7 GHz band:

-126	$dB(W/(m^2 \cdot MHz))$ for $0° \le \delta < 5°$
$-126 + (\delta - 5)/2$	$dB(W/(m^2 \cdot MHz))$ for $5° \le \delta < 25°$
-116	$dB(W/(m^2 \cdot MHz))$ for $25° \le \delta < 90°$

where δ is the angle of arrival above the horizontal plane.

- In the 11.7-12.75 GHz band:

-124	$dB(W/(m^2 \cdot MHz))$ for $0° \le \delta < 5°$
$-124 + (\delta - 5)/2$	$dB(W/(m^2 \cdot MHz))$ for $5° \le \delta < 25°$
-114	$dB(W/(m^2 \cdot MHz))$ for $25° \le \delta < 90°$

where δ is the angle of arrival above the horizontal plane.

3.1.4.1.2 Protection of the fixed service in the 17.7-19.3 GHz band

a) Characteristics of the fixed service systems in the 17.7-19.3 GHz band

The FS characteristics used for the evaluation of pfd limits for non-GSO FSS satellites in the 17.7-19.3 GHz band are given in the following:

Elevation angles	0 and 2.2°
Antenna height	0 metres
Antenna gain	32, 38 and 48 dBi
Antenna pattern	Recommendation ITU-R F.1245
Latitudes	25, 45 and 60°
Gaseous attenuation	Recommendation ITU-R SF.1395
Feeder loss	3 dB
Polarization loss	Note 7 of Recommendation ITU-R F.1245
Receiver thermal noise	-139 dB(W/MHz)

These characteristics are representative of a majority of links in that frequency range.

b) Fixed-service protection criteria in the 17.7-19.3 GHz band

The aggregate FS protection criteria in the 17.7-19.3 GHz band are given as follows in draft new Recommendation ITU-R F.[Doc. 9A/TEMP/64] to be submitted to RA-2000 for approval:

Long term: I/N = -10 dB not to be exceeded for more than 20% of the time.

Short term: I/N = +14 dB not to be exceeded for more than 0.01% of the time.

I/N = +18 dB not to be exceeded for more than 0.0003% of the time.

Note that the short-term criteria were established to protect sensitive FS links.

c) Methodologies used to assess the adequacy of the limits to protect the fixed service in the 17.7-19.3 GHz band

Many analyses using the pfd mask simulation method have been used for assessing the adequacy of the pfd limits for the protection of the FS. In this method, the statistics of the theoretical aggregate power levels received at an FS station are calculated by applying pfd limits under consideration to each visible satellite of the non-GSO FSS constellation. Annex 1 of Recommendation ITU-R F.1108 provides guidance on the calculation of visibility statistics of space stations operating in circular non-GSO orbits as seen by a terrestrial station.

In the derivation of the pfd limits defined in § 3.1.4.1.2 d), it was determined that if the calculated I/N results exceed the criteria of § 3.1.4.1.2 b) by no more than a few dB for worst-case geometries, this does not mean that the FS links would actually be impaired. It must be noted that the pfd mask analysis is overly conservative in that it computes interference (both long term and short term) that exceeds what would be produced by an operating non-GSO FSS system. This is because the analysis assumes that all the visible satellites of the non-GSO FSS constellation radiate simultaneously the maximum pfd limit, in the direction of the FS system under consideration, which is unrealistic. In addition, such an assumption does not take into account the patterns of the real satellite antenna, the power limitations of each satellite or the restrictions that self-interference would impose on a non-GSO system.

Calculations are made assuming that the FS receiver antenna is pointing in the direction of the worst-case azimuth for the non-GSO constellation under consideration, since in that pointing direction, the long-term and short-term power levels generated by the non-GSO constellation into the FS receivers are maximum.

Studies that have considered a more realistic modelling of the problem have produced results providing further evidence supporting that the pfd limits defined in § 3.1.4.1.2 d) are adequate. The method used takes into account some fundamental operational constraints of non-GSO FSS systems by using more realistic downlink models developed to generate pfd distribution profiles for a range of arrival angles which are used in place of the maximum-allowed pfd mask.

Given the methodology and assumptions used for evaluating the pfd limits, it can be assumed that the FS aggregate interference criteria given in draft new Recommendation ITU-R F.[Doc. 9A/TEMP/64], can be applied for each single non-GSO FSS constellation. These conclusions remain valid if the number of co-frequency non-homogeneous non-GSO FSS systems were in the range three to five.

d) Results of studies relating to the review/revision of the power limits appearing in Article S21 in the 17.7-19.3 GHz band

The following per satellite pfd limits (also described in draft new Recommendation ITU-R SF.[Doc. 4-9S/TEMP/94]) (submitted to RA-2000 for approval) are adequate for the protection of the FS in the 17.7-19.3 GHz band from aggregate interference from three assumed non-homogeneous, non-GSO FSS systems. Moreover, the contribution of GSO interference to the sharing has been shown as not being significant. Studies support and validate this conclusion. These results would remain valid if the number of non-GSO FSS systems were in the range three to five.

$-115 - X$	$dB(W/(m^2 \cdot MHz))$ for $0° \le \delta < 5°$
$-115 - X + ((10 + X)/20)(\delta - 5))$	$dB(W/(m^2 \cdot MHz))$ for $5° \le \delta < 25°$
-105	$dB(W/(m^2 \cdot MHz))$ for $25° \le \delta < 90°$

where δ is the angle of arrival above the horizontal plane and X is defined as a function of the number of satellites in the non-GSO FSS constellation, n, as follows:

for $n \le 50$	$X = 0$	(dB)
for $50 < n \le 288$	$X = (5/119)(n - 50)$	(dB)
for $n > 288$	$X = (1/69)(n + 402)$	(dB)

The scaling function, X, was developed on the basis of non-GSO FSS constellations with 96, 288 and 840 satellites. Further simulations with different non-GSO FSS constellations comprising a wide range in the number of satellites (63, 126, 189, 252 and 504 satellites) and using the conservative pfd mask simulation method have confirmed the adequacy of this scaling function.

Extensive studies have provided technical justification that the pfd limits above are certainly adequate to protect the FS from aggregate interference from the satellites of three to five, co-frequency non-GSO FSS systems operating in the 17.7-19.3 GHz band. Therefore these pfd limits are acceptable in that they protect the FS without unduly constraining the development of non-GSO FSS networks.

3.1.4.2 Protection of non-GSO FSS space station receivers from interference caused by FS systems in the 12.75-18.1 GHz frequency range and in the 27.5-28.6 GHz band

Studies have been undertaken to evaluate the interference from fixed-service systems into non-GSO FSS space stations in the bands where the two services are allocated on a co-primary basis in the 12.75-18.1 GHz frequency range and in the 27.5-28.6 GHz band.

3.1.4.2.1 12.75-18.1 GHz frequency range

The study was based on the characteristics of typical FS point-to-point systems and on the characteristics of the space stations of F-SAT MULTI 1B non-GSO FSS system. The study concluded that, even under pessimistic assumptions, the interference from FS systems into non-GSO FSS (Earth-to-space) in the 12.75-18.1 GHz frequency range would be acceptable.

3.1.4.2.2 27.5-28.6 GHz band

The study was based on the characteristics of typical FS point-to-multipoint systems and on the characteristics of the space stations of LEOSAT-1 non-GSO FSS system. The study considered the interference from high deployment of FS subscribers terminals into the main beam and the near side lobes of the non-GSO FSS satellite antenna. This study concluded that the interference levels would be acceptable since they are significantly lower than the generally agreed criterion. However, the study did not consider the aggregate impact of all transmitters located within the entire portion of the Earth visible to the satellite, the interference from a terminal's main beam into the side lobes of the satellite, or the interference between the FS hub transmitters using sectoral antennas into the non-GSO FSS satellite receiver. There was also concern expressed with the assumptions used in the study that might not be worst case in terms of transmit power levels or elevation angles. On this basis, further studies would be required before definitive conclusions can be reached.

It must also be noted that the current RR allow higher e.i.r.p. values to be transmitted in this band than the P-MP FS stations studied in this paper. Limits of 10 dBW on the transmit power and 55 dBW on the e.i.r.p. are specified in Article **S21** and Recommendation ITU-R SF.406, with no restriction placed on the bandwidth or elevation angle. Therefore, there may be a need to review the e.i.r.p. limits considering bandwidth and elevation angle for FS transmitters operating in this band.

3.1.4.3 Sharing between non-GSO FSS earth stations and fixed-service stations

The deployment needs of viable FS and FSS services range from sparse, low density to increasingly higher density. This affects the sharing conditions in terms of coordination between fixed stations and FSS earth stations. At one extreme is the low-density deployment of both services, which facilitates sharing. At the other extreme is the high-density deployment of both services, which creates the most difficult sharing environment. In this instance, either one or both services may be excessively constrained or prevented from offering a viable service in the same geographical area.

In the 10-30 GHz range, the fixed service applications are rapidly evolving to support cellular and PCS infrastructures as well as direct access to business and residential subscribers. There are also proposals for high-density FSS earth station applications. Some administrations are considering the authorization of such systems using area-wide (blanket) licensing. Such licensing schemes lead to a requirement for new approaches in order to facilitate sharing.

The case of sharing between FS and non-ubiquitous FSS earth stations can be handled through classical case-by-case coordination procedures which have already proved to work successfully. In the case of deployment of ubiquitous FSS terminals, in principle, the use of mitigation techniques by one or both services improves the ability of those services to share the same frequency bands.

The feasibility of potential mitigation techniques and their relative effectiveness are currently being studied. This involves a wide range of technical, economic and regulatory trade-offs. In cases where mitigation is insufficient or not practicable in those bands that are already or planned to be heavily used by the one type of service, possible solutions range from frequency separation to constraining the introduction of the other type of service to low-density, non-ubiquitous applications. However, so far, there is no practical experience to demonstrate fully unconstrained, co-frequency deployment of both FS and non-GSO FSS terminals is feasible, where the deployment of either system is of an ubiquitous nature. Furthermore, as the density of either service grows, the effectiveness of mitigation techniques decreases.

If either the FS or FSS deploys terminals in an unconstrained ubiquitous manner, co-frequency sharing in the same geographic area would be very difficult. However, this is a national issue except in the vicinity of international borders, where coordination between administrations may be required.

3.1.4.4 Sharing between non-GSO FSS and RLS, RNS and SRS in the bands 13.75-14 GHz and 17.3-17.7 GHz

3.1.4.4.1 Characteristics of the non-GSO FSS, radiolocation, radionavigation and space research systems

13.75-14.0 GHz

The band 13.75-14 GHz is allocated on a co-primary basis to FSS, RLS. It is also allocated, in some countries, to FS and MS (Nos. **S5.499** and **S5.500**) and to RNS (No. **S5.501**). GSO systems of SRS use this band in accordance with No. **S5.503**. Additionally, non-GSO SRS and EESS operate with protection from the FSS (No. **S5.503A**) until 1 January 2000. After 2001 the only space research system that will remain in the band on a co-primary basis with the FSS is the DRS system. For the sharing between FSS, RLS, RNS and SRS, the 13.75-14 GHz band can be split as follows:

- 13.75-13.8 GHz: FSS uplinks, RNS, radiolocation emissions and GSO-DRS links to both earth stations and LEO spacecraft (e.g. Shuttle);
- 13.8-14 GHz: FSS uplinks, RNS, radiolocation emissions and GSO-DRS links to earth stations only.

Technical and operational characteristics of radiolocation stations in the band 13.75-14 GHz are described in Recommendation ITU-R S.1068. These radars have peak e.i.r.p.s of 79 dBW and average e.i.r.p.s of 59 dBW and operate in both scanning and tracking modes. They are predominately shipborne radars, but some are land based. It is estimated that there are about 600 radars of this type in operational use.

17.3-17.7 GHz

The band 17.3-17.7 GHz is allocated to the RLS on a secondary basis, to FSS on a primary basis (limited by **S5.516** to BSS feeder links) and, in Region 2, to the BSS beginning 1 April 2007. Numerous types of radiolocation stations operate in the band 17.3-17.7 GHz. These stations include ship, ground and airborne equipment, some of which are tracking objects in space. These space-tracking radars could cause an instantaneous e.i.r.p. of 116 dBW to be directed at a satellite and may at times track it. These radars are also pointed at zenith and off-zenith for lengthy periods to provide maintenance of the space object catalog and data for space debris analysis and mapping. Although there are no limits imposed on radars in the band 17.3-17.7 GHz, sharing between BSS feeder links and the RLS is currently feasible if the radiolocation service limits the e.i.r.p. towards the GSO to approximately 50 dBW. Emissions could be 66 dB higher toward a non-GSO satellite than toward the GSO.

3.1.4.4.2 Protection criteria

At WARC-92 and WRC-95, Nos. **S5.502**, **S5.503** and **S5.503A** were added to the Table of Frequency Allocations to facilitate compatibility between the existing applications in these services. It was agreed that any modifications to any of these footnotes in order to accommodate new technology, new requirements and applications of the FSS should consider the overall interference environment in the 13.75-14 GHz band and be undertaken with great care in order to avoid upsetting the delicate balance previously achieved between the services. The present operational constraints, that satisfy the protection criteria of current operational applications and technology in the band 13.75-14 GHz, are to be found in Nos. **S5.502** and **S5.503**.

The protection criteria of the space research links used are those included in Recommendation ITU-R SA.1155.

3.1.4.4.3 Methodologies used to assess the adequacy of the protection of non-GSO FSS, RLS, RNS and SRS

Regarding the impact of radiolocation transmissions on non-GSO FSS applications, the methodology used is similar to that given in Recommendation ITU-R S.1068, assuming the characteristics given in that Recommendation together with additional parameters provided by relevant ITU-R Study Groups. Extensive analyses were also performed on space science and non-GSO FSS systems compatibility based on the space research and F-SAT MULTI 1B characteristics.

3.1.4.4.4 Results of studies

These technical analyses have led to possible solutions which will maintain the present balance in the sharing conditions between radiolocation, space science and FSS, and accommodate non-GSO/FSS systems within the 13.75-14 GHz band.

With reference to No. **S5.502**, reduction or suppression of the minimum e.i.r.p. requirement for FSS earth stations coupled with appropriate regulatory measures to address the concerns of the radiolocation services, could achieve this objective. Under the current provisions, provided a radar observes the restriction put on its maximum e.i.r.p. averaged over 1 second, the FSS cannot claim protection from the radiolocation service regardless of the FSS earth station e.i.r.p. used.

Further analyis is needed to better define the interference environment of non-GSO FSS systems with regard to radiolocation emissions. In reviewing the radar characteristics provided in Recommendation ITU-R S.1068, clarification is needed on the possibility of extending the maximum e.i.r.p. averaged over one second from the GSO arc direction to the whole space.

In the case of footnote No. **S5.503** the present balance could be maintained through the addition of a maximum e.i.r.p. requirement of 51 dB(W/6 MHz) and a minimum antenna diameter of 4.5 m placed on the non-GSO FSS earth station in the band 13.772-13.778 GHz, combined with other appropriate regulatory provisions taking into consideration the overall interference environment in the 13.75-14 GHz band.

Other possibilities have been considered in order to assess how a relaxation of present operational constraints on the different services could be obtained and how more flexibility could be afforded to the different applications within the services. These possibilities require further studies within the

ITU-R. Information was given that future development of radars in this band may need a higher average e.i.r.p. limit, the impact of which would require a study. Some studies have been brought to the attention of the CPM about the sharing conditions between GSO FSS services and radiolocation in the band 13.75-14 GHz and between GSO FSS services and space research in the band 13.772-13.778 GHz. These studies related to the possible relaxation of the minimum antenna diameter of 4.5 m contained in footnote **S5.502**. Reconsideration of this limit requires further study within ITU-R.

In the band 17.3-17.7 GHz some analyses have been carried out on the basis of the radar characteristics available. Under the assumptions that there were few high power radars (maximum e.i.r.p. 116 dBW) and that the maximum pulse duration was 256 μs, it was found that a system like F-SAT MULTI 1B could handle such interference. Since these radars may at times track non-GSO space stations, more information needs to be made available on the operational characteristics of the high power radars in order to determine more accurately the impact of the radar on non-GSO FSS systems.

3.1.4.5 Regulatory and procedural considerations

3.1.4.5.1 Fixed service and non-GSO FSS systems

Resolution **131 (WRC-97)** invites ITU-R to study the appropriate pfd values to be applied to non-GSO networks in the bands 10.7-12.75 GHz and 17.7-19.3 GHz to ensure protection of the fixed service without unduly constraining the development of either type of network. Additionally, text is needed to reflect *resolves* 2 of Resolution **131 (WRC-97)** in Article **S.21**. Annex 4 provides an example of possible modifications of Article **S21**, Table **S21-4** including consideration of *resolves* 2 of Resolution **131 (WRC-97)**.

3.1.5 Identification and validation of software which could be used by the BR to check whether a system for which application for spectrum has been made would comply with the APFD and EPFD limits

The equivalent power flux-density (EPFD) limits apply to the sum of all emissions from the space stations (for $EPFD_{down}$ or $EPFD_{is}$) and earth stations (for $EPFD_{up}$) of a non-geostationary orbit (non-GSO) satellite system. Furthermore, the limits are specified for various percentages of time and as a function of GSO antenna characteristics. This complex combination precludes the use of a formula to determine compliance with the limits. Software can be used to accumulate the statistics of EPFD for any proposed non-GSO system and then compare these statistics with the limits and time percentages in the RR. Draft new Recommendation ITU-R BO.[Doc. 11/136] provides a functional description of the BR software, including sections on testing, documentation, and verification of the software. One or more candidate software programs that comply with this specification should be available for BR to evaluate prior to WRC-2000 and selection of software to be used for EPFD compliance testing should be approved at WRC-2000.

3.1.5.1 Summary of specification for the software

Draft new Recommendation ITU-R BO.[Doc. 11/136] provides the specification for the software which the BR/ITU would use to verify that a non-GSO network meets the $EPFD_{down}$/$EPFD_{up}$/$EPFD_{is}$ limits. This specification has been made available to administrations.

A software implementation that includes all the inputs, functions, and outputs described draft new Recommendation ITU-R BO.[Doc. 11/136] would enable BR to check compliance of any non-GSO system with the EPFD limits. Input parameters include the following:

- reference parameters (earth station and space station reference antenna radiation patterns, etc.);
- inputs from the appendix **S4** supplied by the administration for the non-GSO system;
- GSO earth station location test points.

The block diagram of the software algorithm is shown in Fig. 3-3. It consists of two sections: that of Initial Data and that of Calculation. The Initial Data Section contains the whole set of parameters relevant to the notified non-GSO satellite system, a set of reference GSO system parameters as well as $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits. The Calculation Section is designed for estimations required to examine notified non-GSO systems compliance with the $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits. The Calculation Section is based on a concept of a downlink pfd mask[2], an uplink e.i.r.p. mask[3], and an inter-satellite pfd mask[4].

A pfd/e.i.r.p. mask is calculated in Block 1 based on the notified non-GSO system parameters delivered from the Initial Data Section. Block 4 tests the aggregate interference produced by non-GSO network stations for meeting $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits. The verification in Block 4 is effected on the basis of the non-GSO system constellation characteristics from the Initial Data Section, a pfd/e.i.r.p. mask from Block 1 and output data from Block 3. The output data are verified for validity in Block 2.

Taking into account the significant complexity regarding specific features of different non-GSO system configurations in the software it would seem appropriate to impose some burden of responsibility relevant to testing for $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits on administrations notifying appropriate non-GSO systems. Therefore the examination procedure for meeting $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits would consist of two stages. The first stage would include the software development (Block 1) and conducting all the calculations by the administrations notifying non-GSO satellite systems. The stage would also include estimation of a mask for pfd/e.i.r.p. produced by interfering non-GSO network stations. The mask would account for all the features of specific non-GSO systems arrangements. The first stage would be finalized with delivering the pfd/e.i.r.p. mask in analytical or documented formats to the BR/ITU. Moreover the notifying administration would provide the BR/ITU with the software used in Block 1 for the pfd/e.i.r.p. mask estimation, the complete software description and parameters from Block "a": the information will also be available to other administrations.

The second stage calculations would be effected at the BR/ITU. The second stage would feature the following operations:

1) Definition of the maximum EPFD geometry of a GSO space station and an earth station of that network (Block 3). It would ensure verification of sharing feasibility for a notified non-GSO network with any GSO network in the FSS and BSS.
2) $EPFD_{down}/EPFD_{up}/EPFD_{is}$ statistics estimation (Block 4).
3) Software results verification for validity (Block 2).
4) Making a decision on interference compliance with $EPFD_{down}/EPFD_{up}/EPFD_{is}$ limits (Block 4).

---

[2] A pfd mask is the maximum pfd produced by a non-GSO space station.

[3] An e.i.r.p. mask is the maximum e.i.r.p. radiated by a non-GSO earth station and is a function of the off-axis angle from the transmitting antenna main beam.

[4] This is the maximum e.i.r.p. radiated by a non-GSO space station and is a function of the off-axis angle from the transmitting antenna main beam.

The estimations are based on the non-GSO system parameters (Block "a") delivered by a notifying administration and the initial data (Block "b") available at the BR/ITU.

Any administration may use as required software that uses the algorithms defined in this document together with data on the non-GSO networks to estimate statistics for interference into its own GSO networks and check for compliance with $EPFD_{down}$/$EPFD_{up}$/$EPFD_{is}$ limits.

For checking compliance with these limits, BR will use certain increments and will test against the more fractionally severe value. For example, if the increment is 0.1 dB, where the $EPFD_{down}$ limit is -165.841 dB(W/(m^2.40 kHz)) the software will test against a criterion of -165.9 dB(W/(m^2.40 kHz)). The same rules should be applied when computing the $EPFD_{down}$ statistics.

3.1.5.2 Software validation process

Several administrations and other organizations are understood to be developing such software.

The candidate software shall be tested for accuracy using the guidelines stated in Annex 1 of draft new Recommendation ITU-R S.[Doc. 11/136]. The procedures given in draft new Recommendation ITU-R S.[11/136] shall be used for the validation of the candidate software.

In order to allow sufficient time for the BR to evaluate the candidate software and prepare its report, administrations have been requested to supply the candidate software to the BR by mid-January 2000.

3.1.5.3 Further work required

Upgrading of the software would be necessary to take account of decisions of future radio conferences.

3.1.6 Regulatory procedures for the implementation of aggregate and operational limits

3.1.6.1 Aggregate limits

Section 3.1.1.3.2 identifies the need for a regulatory mechanism that would ensure protection of GSO FSS and GSO BSS networks from the maximum aggregate equivalent power flux-density produced by multiple non-GSO FSS systems in frequency bands where EPFD validation limits have been adopted. One possible mechanism for meeting this objective is a WRC-2000 Resolution that would take the form of the example draft Resolution (example Resolution **WWW**).

It was noted that Resolution **WWW** involves circumstances where several non-GSO administrations may need to jointly address interference concerns where it may be difficult for them to collectively resolve the problems in an expeditious manner. Furthermore, there is no recourse in the case of inability to reach agreement. An example procedure is included as section 1 in Annex 8 to this Chapter.

It is noted that in Steps 2) and 6) of section 1 in Annex 8, there are references to an [X] day period representing the requirement for "expeditious" resolution of an excess operational EPFD situation. The value of X is not yet agreed, but it should reflect the need for expeditious action, taking into account administrative and mailing delays.

Also, in section 1 in Annex 8, no conclusion was reached in the case of an administration failing to respond to BR request for cooperation. There needs to be further discussion on choosing the appropriate remedial measures, for the purpose of including such measures as Step 8) in the procedure. Some administrations were of the view that Step 8) could be replaced by the following: "In case the administration fails to respond to BR's request for information, BR shall commence with proceedings to cancel the entry of the relevant non-GSO network(s) from the Master Register". The view was also expressed that the procedures should be included in Article **S15**, or in a new stand-alone Article **[S15A]** or in a WRC Resolution. A further view was expressed that such procedures should be extended to any situation where permissible/accepted interference levels are exceeded or where the provisions of No. **S22.2** are not satisfied.

Administrations as well as BR are invited to review the practicability of the procedure outlined.

3.1.6.2 Operational limits

Section 3.1.2.4.7 defines "Operational Limits" to the $EPFD_{down}$ by non-GSO systems in certain frequency bands. This section also notes that additional regulatory work to develop a procedure based on this concept may be needed. In order to implement the operational limit concept, a procedure is needed which: i) identifies non-GSO systems exceeding the operational limits; and ii) ensures immediate reduction of the interference level to the operational limits by any non-GSO system exceeding those limits. It may be appropriate for this procedure to include the possibility of arriving at an alternative permanent solution acceptable to both parties. An example procedure is given in section 2 to Annex 8 to this Chapter.

Also, no conclusion was reached in the case of an administration failing to respond to BR request for cooperation. There needs to be further discussion on choosing the appropriate remedial measures, for the purpose of including such measures as Step 7) in the procedure in section 2 to Annex 8. Some administrations were of the view that Step 7) could be replaced by the following: "In case the administration fails to respond to BR's request for information, BR shall commence with proceedings to cancel the entry of the relevant non-GSO network(s) from the Master Register". The view was also expressed that the procedures should be included in Article **S15**, or in a new stand-alone Article [S15A] or in a WRC Resolution. A further view was expressed that such procedures should be extended to any situation where permissible/accepted interference levels are exceeded or where the provisions of No. **S22.2** are not satisfied.

Administrations as well as BR are invited to review the practicability of the procedure outlined.

****

3.2 Agenda item 1.13.2

"to consider the inclusion in other frequency bands of similar limits in Articles **S21** and **S22**, or other regulatory approaches to be applied in relation to sharing situations"

3.2.1 Sharing considerations between non-GSO FSS and GSO BSS receive earth stations in the 17.3-17.8 GHz band

Resolution **538 (WRC-97)** introduced provisional EPFD and $EPFD_{up}$ limits for non-GSO FSS systems in certain bands intended to protect GSO BSS systems. Resolution **538 (WRC-97)** did not designate use of the 17.3-17.8 GHz band in Region 2 by non-GSO FSS, stating that such use required further study as to the feasibility of non-GSO FSS to share with the allocated BSS service in this band. The ITU-R considered the sharing situations identified in Resolution **538 (WRC-97)**.

Regarding sharing between transmit GSO BSS space stations and receive non-GSO FSS space stations, it was concluded that there would be no need for specific provisions since the sharing situation would be similar to that existing between GSO FSS transmit space stations and non-GSO FSS receive space stations in the adjacent band 17.8-18.4 GHz.

Regarding the feasibility of sharing between transmitting non-GSO FSS earth stations and ubiquitous BSS receive earth stations in the 17.3-17.8 GHz band, it was noted that this situation would require coordination, using the existing provisions under **S9.17A**, between the administrations on the territories of which the non-GSO FSS transmitting earth stations and BSS receive earth stations are located. It was also noted that the frequency band 17.7-17.8 GHz is also allocated to the fixed-satellite service (space-to-Earth).

It was concluded that sharing is not feasible between ubiquitous non-GSO FSS user terminals and ubiquitous BSS receive terminals located in the same geographical area.

Regarding non-GSO gateway operation, the studies reported to the ITU-R concluded that the coordination distance with BSS receive terminals would be the default value of 100 km. This means that coordination would have to take place between administrations when the distance between a non-GSO gateway and the territory of another administration intending to deploy BSS receive terminals is smaller than 100 km. During this coordination the separation distances required to avoid unacceptable interference would be assessed.

One study determined the separation distance to be between 15.8 and 93.9 km for non-GSO FSS gateways for the particular system studied (F-SAT MULTI 1B).

It was based on:

- A steady state long-term protection criterion of I/N = -18 dB. This value was selected to provide sufficient protection of the GSO BSS from non-GSO FSS when the interfering source is not time varying.
- A 2.5 m non-GSO gateway antenna with a minimum 10° elevation angle.

- Use of both a worst-case and best-case relative azimuth angle between the source and victim antennas, bounding the time varying nature of the interference.
- A free space loss propagation model.

Further analysis was performed based on ITU-R agreed protection criteria developed for sharing between GSO BSS and non-GSO FSS downlinks again assuming the non-GSO FSS earth station operates at 10° minimum elevation angle. The I/N value used in the calculations corresponds to an increase in unavailability of the BSS link of 2.86% (10% ÷ 3.5 effective non-GSO FSS systems).

Using this long-term criteria, this study calculated a separation distance of 65 km. It was noted that the acceptable interference level used was derived assuming the wanted and interfering signals were equally faded. In actual practice, the BSS signal can be faded while the gateway interference may not be faded. This will lead to the need for larger separation distances.

Another study to assess the required separation distance considered the same non-GSO FSS system (F-SAT MULTI 1B) and was based on:

- the statistical method included in the draft new Recommendation ITU-R S.[Doc. 4/60] that is being considered for possible inclusion in Appendix **S7** to deal with non-GSO FSS earth station interference; and
- the I/N criterion of 8 dB not to be exceeded for more than 0.003% of the time. This I/N is 1.3 dB less conservative than the upper bound I/N range of the current preliminary criteria to calculate the coordination contour.

This study concluded that, for a 0° horizon elevation around a non-GSO FSS gateway, the separation distances for the gateways of this particular system are typically 20 km, ranging from 1 km to 45 km, depending on the azimuths considered around the gateway. It also showed that, for a particular case assuming a 1° horizon elevation around the gateway in every direction (i.e. 20 m horizon height at a 1 km distance), this separation distance would fall to 1 km in all directions.

The difference in the results of the above studies are due to the difference in BSS criteria, propagation models and methodologies used. These criteria and methodologies used for separation distance calculation, are provisional pending the adoption of final criteria and methodologies within ITU-R.

One result from these studies is that in order to avoid interference from non-GSO gateway terminals within or near a BSS service area, some separation distance is required between the gateway terminal and ubiquitously deployed BSS receive terminals. BSS user terminals located closer to the non-GSO gateway terminal than the required separation distance would not receive unconstrained interference-free service. These terminals would require special treatment on an installation-by-installation basis to ensure service to all BSS users.[5]

Views were expressed that, since the BSS, by definition, is intended for general reception by the public and therefore dependent on the ability to ubiquitously deploy receive earth stations, reception within the BSS service area should not be limited or restricted, therefore non-GSO FSS use of the 17.3-17.8 GHz band in Region 2 would not be feasible.

[5] BSS receive terminals that will operate in the 17.3-17.8 GHz band may have to share the band with Appendix **S30A** BSS feeder-link earth stations depending upon the implementation of BSS in the 17 GHz band by each Region 2 administration. The BSS feeder links are quite limited in number, operate towards relatively fixed positions in space, and typically not towards the horizon. The band 17.7-17.8 GHz is also allocated to the FSS (s-E) and the FS.

Several views were also expressed that, given that the number of non-GSO FSS gateways proposed in this band would not be large, and given the small separation distances shown in the second study, the use of non-GSO FSS gateway transmit earth stations in this band would be feasible without undue constraints on the development of GSO BSS.

3.2.2 Frequency band 17.3-17.8 GHz

The question was raised as to whether the 17.3-17.8 GHz band was allocated for use by the non-GSO FSS in Region 2 at WRC-97. Reference was made to footnote **S5.516** which states:

S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8-18.1 GHz (Earth-to-space) in Region 2 by non-geostationary-satellite systems in the fixed-satellite service is subject to the provisions of Resolution **538 (WRC-97)**.

Some administrations consider that it was not the intent of WRC-97 to make this band available for the non-GSO FSS (uplink) in Region 2 and that this allocation is not effected by the footnote.

Other administrations consider the footnote to mean that an allocation is available in this band for non-GSO FSS (uplink) use and that only further sharing studies are required.

The question was submitted by one administration to the RRB requesting the Board to prepare a Rule of Procedure stating that the band 17.3-17.8 GHz is not allocated to the non-GSO FSS (uplink) in Region 2. At the Board's 18th meeting 8-12 November 1999 the Board considered this matter and concluded that "***... a Rule of Procedure was not necessary in this case***". Presumably it is being left to WRC-2000 to take any action that is deemed necessary on this matter.

Should WRC-2000 decide that the band 17.3-17.8 GHz is allocated to non-GSO FSS (uplink) in Region 2 it is proposed that the -160 dB(W/(m^2.40 kHz)) $EPFD_{up}$ limit should also be applicable to the frequency band 17.3-17.8 GHz (Region 2) in order to protect BSS feeder links from non-GSO FSS (uplinks) in Region 2 (see also 3.1.3.1.4).

It was recognized that there is currently an allocation to BSS in Region 2 in the frequency band 17.3-17.8 GHz, allocation entering into effect on 1 April 2007 (No. **S5.517**). If power limits were to be used for sharing between non-GSO BSS systems in Region 2 and GSO BSS feeder links, the single entry $EPFD_{is}$ applicable to the frequency band 17.8-18.1 GHz (-160 dB(W/m^2·40 kHz) would be appropriate in the frequency band 17.3-18.1 GHz.

3.2.3 18.1-18.4 GHz band

The ITU-R examined the possibility of applying $EPFD_{up}$ limits in the band 18.1-18.4 GHz, intended to protect GSO BSS feeder links in this band from interference caused by non-GSO FSS systems operating in the Earth-to-space direction.

It was noted that the sharing and regulatory situations in the 17.8-18.1 GHz band and in the 18.1-18.4 GHz band currently differ only on the following aspects:

- In the 17.8-18.1 GHz band, sharing between BSS feeder links and non-GSO FSS (Earth-to-space) is effected by the $EPFD_{up}$ limits which have been reviewed ITU-R.
- In the 18.1-18.4 GHz band, sharing between BSS feeder links and non-GSO FSS (Earth-to-space) is effected by the application of No. **S22.2**.

As No. **S5.520** currently restricts the use of this band by FSS (Earth-to-space) to BSS feeder links, the use of this band by non-GSO FSS (Earth-to-space) other than BSS feeder links would therefore require a modification to this footnote.

It was also concluded that there would be a need to include $EPFD_{up}$ limits in Article **S22** to protect GSO BSS feeder links in this band, if WRC-2000 decides that this band may be used by non-GSO FSS Earth-to-space other than BSS feeder links. The level considered appropriate for these limits to protect GSO BSS feeder links is that proposed by in Annex 1 for the $EPFD_{up}$ limits in the adjacent band (17.8-18.1 GHz) and for $EPFD_{is}$ limits in the 18.1-18.4 GHz band.

The ITU-R also noted that no regulatory approaches other than the power limits approach were studied or proposed for this band. Regulatory approaches other than power limits may also be considered.

Concerns were raised about the impact of coordination distances required between non-GSO FSS transmitting earth stations and receiving FSS earth stations on the ability to ubiquitously deploy receiving terminals in the FSS in this band. It was noted however, that the selection of either type of service in a particular country is a matter of national decisions. In the case of non-GSO FSS transmitting gateways, coexistence with other FSS receiving terminals in neighbouring countries could be ensured through bilateral coordination, when necessary.

With regard to the fixed service, studies have been undertaken to evaluate the interference from fixed service systems into non-GSO FSS space stations in the 18.1-18.4 GHz band, where the two services are allocated on a co-primary basis. The studies were based on the characteristics of typical FS point-to-point systems and on the characteristics of the space stations of the F-SAT MULTI 1B non-GSO FSS system. The study concluded that, even under pessimistic assumptions, the interference from FS systems into non-GSO FSS (Earth-to-space) in the 18.1-18.4 GHz frequency range would be acceptable. However, the ITU-R notes that studies on the potential interference to FS receiving stations from non-GSO FSS transmitters have not been completed. . Therefore, the possible introduction of limits in the 18.1-18.4 GHz band would be considered after these studies have been completed.

3.2.4 Frequency outside of range 10-30 GHz

When it adopted Resolution **130 (WRC-97)** and the provisional limits that would apply to non-GSO FSS systems in certain bands between 10 and 30 GHz, WRC-97 determined that for these specific bands, non-GSO systems in the FSS should bear more of the burden of accommodating sharing than should co-frequency GSO FSS systems. WRC-97 did not decide how to assign sharing burdens between GSO and non-GSO systems in any FSS bands above 30 GHz or below 10 GHz, but instead requested that the ITU-R "undertake the development of power limits or other frequency sharing mechanisms" - at least in such bands where non-GSO FSS systems are likely to be implemented and GSO systems are used or expected to be used extensively. This direction is consistent with § 4.3.7.2 of the CPM-97 Report, which recognized that a power limits approach of the type that is now reflected in Resolution **130 (WRC-97)** "is not suited for sharing situations where more burden would be placed on the GSO FSS systems or the burden would be equally shared between the GSO and non-GSO ... systems," and that the "establishment of e.i.r.p. and pfd limits may not be a suitable approach for all types of non-GSO ... networks in every FSS band."
There are fundamental differences between the situation in the 10-30 GHz FSS bands identified in Resolution **130 (WRC-97)** where a non-GSO FSS service concept is being overlaid upon an existing and/or imminent GSO FSS service and other bands where both GSO and non-GSO FSS systems are just now beginning to emerge. In these 10-30 GHz bands, there is extensive deployment or long-standing development of GSO systems and GSO operators have limited or no flexibility to

adjust to the introduction of non-GSO systems. In these bands, non-GSO systems must thus bear most or all of the burden of implementing technical criteria to protect the GSO arc. In bands where there has been little or no deployment of satellite systems to date and satellite networks (GSO and non-GSO alike) have only recently begun to be communicated to ITU-R, the absence of current and imminent use by GSO and non-GSO FSS systems means that both types of operators should expect to exhibit greater flexibility in achieving the appropriate balance among the competing technical, regulatory and policy considerations that will affect their sharing environment.

Technical studies of interference mitigation techniques that may be employed by non-GSO and/or GSO FSS operators in bands outside 10-30 GHz to enable co-frequency sharing are under way in ITU-R. Simulation results on a planned non-GSO FSS system in the 40-50 GHz band were provided, analysing the impact of two mitigation techniques. The first set of results assumed polarization discrimination between the GSO and the non-GSO systems. To use this mitigation technique, the non-GSO system has to be on the opposite polarization from every GSO system with which it will have in-line events. The second set of results assumes that the GSO satellite can also use satellite diversity as an interference mitigation technique. This technique would improve the GSO link availability and increase the system capacity because the propagation impairments at these frequency bands are severe. Both techniques proved to be efficient in mitigating the mainbeam-to-mainbeam interference that can appear between non-GSO and GSO systems operating co-frequency in these bands. However, both would constrain the GSO FSS to either use only one polarization or to double the number of satellites required.

Although the techniques examined in bands outside 10-30 GHz offer promise in mitigating the mainbeam-to-mainbeam interference that can appear between co-frequency non-GSO and GSO systems, further work needs to be done on these potential mitigation techniques and other approaches and refinements that have yet to be addressed within ITU-R. Matters that remain to be addressed in these bands include whether there would be coordination between non-GSO and GSO systems, the appropriateness of retaining No. **S22.2**, the impact of other co-frequency services in a particular band on the GSO/non-GSO sharing situation and the impact of any regulatory approach for GSO and non-GSO sharing on innovation in all services in a particular band.

As a result, ITU-R is not in a position to make a final recommendation on whether power limits on the non-GSO FSS operator or some other frequency sharing mechanism or combination of mechanisms should be imposed to facilitate GSO/non-GSO FSS sharing in any FSS band outside the 10-30 GHz range. There is no technical basis at this time for extending to FSS bands above 30 GHz and below 10 GHz either the regulatory scheme that is established in Resolution **130 (WRC-97)** for certain FSS bands between 10 and 30 GHz or any other regulatory/procedural approach (e.g. Resolution **46 (Rev. WRC-97)/S9.11A**). The regulatory scheme in Resolutions **130 (WRC-97)** and **538 (WRC-97)** reflects the particular circumstances at 10-30 GHz and is inappropriate for application by default to the very different circumstances that exist in the FSS bands above 30 GHz and in certain of the FSS bands below 10 GHz.

Regarding the possible introduction of limits in bands outside of the range 10-30 GHz, insufficient proposals have been received by the ITU-R Study Groups to allow the introduction of limits or alternative regulatory approaches in other bands.

3.2.5 Other regulatory approaches

A number of studies considered by ITU-R presented the per-satellite pfd approach as an approach to enable sharing between GSO and non-GSO FSS systems. However, there is concern that the current form of per-satellite pfd limits would unacceptably constrain the design flexibility of non-GSO FSS systems. Further study is required before this per-satellite pfd approach may be considered to be a viable regulatory option.

ANNEX 1 TO CHAPTER 3

Example of possible modifications to Section II of Article S22

ARTICLE S22

Space services[1]

Section II – Control of interference to geostationary-satellite systems

NOC S22.2 to S22.5A

SUP S22.5B

Existing texts from **S22.5C** to **S22.5G**, including **S22.5C.1** and **S22.5D.1,** are proposed to be replaced by the provisions below as modified from the draft CPM text.

MOD S22.5~~C~~B § 5 1) The equivalent power flux-density[2], $EPFD_{down}$ at any point on the Earth's surface visible from the geostationary-satellite orbit, produced

[1] **A.S22.1** In applying the provisions of this Article, the level of accepted interference (see No. **S1.168**) shall be fixed by agreement between the administrations concerned, using the relevant ITU-R Recommendations as a guide.

[2] **S22.5~~C~~B.1, C.1, D.1** The equivalent power flux-density is defined as the sum of the power flux-densities produced at a GSO receive station~~point~~ on the Earth's surface or in the geostationary orbit, as appropriate, by all the transmit ~~space~~ stations within a non-geostationary-satellite system, taking into account the off-axis discrimination of a reference receiving antenna assumed to be pointing ~~towards the geostationary-satellite orbit~~in its nominal direction. The equivalent power flux-density is calculated using the following formula:

$$\cancel{epfd = 10 \cdot \log_{10}\left[\sum_{i=1}^{N_s} 10^{pfd_i/10} \cdot \frac{G_r(\theta_i)}{G_{max}}\right]}$$

$$EPFD = 10 \cdot \log_{10}\left[\sum_{i=1}^{N_a} 10^{\frac{P_i}{10}} . \frac{G_t(\theta_i)}{4.\pi d_i^2} . \frac{G_r(\phi_i)}{G_{r,\max}}\right]$$

where:

N_a is the number of transmit stations in the non-geostationary-satellite system that are visible from the GSO receive station considered on the Earth's surface or in the geostationary orbit, as appropriate;

i is the index of the transmit station considered in the non-geostationary-satellite system;

by emissions from all the space stations of a non-geostationary-satellite system in the fixed-satellite service in the frequency bands listed in Tables ~~S22-1,~~ S22-1A to S22-1D, including emissions from a reflecting satellite, for all conditions and for all methods of modulation, shall not exceed the limits given in Tables ~~S22-1~~ S22-1A to S22-1D for the given percentages of time. These limits relate to the equivalent power flux-density which would be obtained under free-space propagation conditions, into a reference antenna and in the reference bandwidth specified in Tables ~~S22-1~~ S22-1A to S22-1D, for all pointing directions towards the geostationary-satellite orbit. ~~(WRC-97)~~

P_i is the RF power at the input of the antenna of the transmit station, considered in the non-geostationary satellite system in dBW in the reference bandwidth;

θ_i is the off-axis angle between the boresight of the transmit station considered in the non-geostationary satellite system and the direction of the GSO receive station;

$G_t(\theta_i)$ is the transmit antenna gain (as a ratio) of the station considered in the non-geostationary satellite system in the direction of the GSO receive station;

d_i is the distance in metres between the transmit station considered in the non-geostationary satellite system and the GSO receive station;

ϕ_i is the off-axis angle between the boresight of the antenna of the GSO receive station and the direction of the ith transmit station considered in the non-geostationary satellite system;

$G_r(\phi_i)$ is the receive antenna gain (as a ratio) of the GSO receive station in the direction of the ith transmit station considered in the non-geostationary satellite system;

$G_{r,max}$ is the maximum gain (as a ratio) of the antenna of the GSO receive station;

$EPFD$ is the computed equivalent power flux-density in dB(W/m^2) in the reference bandwidth.

~~N_s: number of non-geostationary space stations visible from the point considered at the Earth's surface, within an elevation angle greater than or equal to 0°;~~

~~i: index of the non-geostationary space station considered;~~

~~pfd_i: power flux-density produced at the point considered on the Earth's surface in dB(W/m^2) in the reference bandwidth;~~

~~θ_i: angle between the direction considered towards the geostationary-satellite orbit and the direction of the interfering space station in the non-geostationary-satellite system;~~

~~$G_r(\theta_i)$: gain (as a ratio) of the receive reference antenna to be considered as part of a geostationary-satellite network;~~

~~G_{max}: maximum gain (as a ratio) of the above receive reference antenna;~~

~~$epfd$: computed equivalent power flux-density in dB(W/m^2) in the reference bandwidth.~~

~~TABLE S22-1 (WRC-97)~~

~~Frequency band allocated to the broadcasting-satellite service~~	~~Antenna diameter (cm)~~	~~Equivalent pfd level (dB(W/m²/4 kHz)) which may not be exceeded during the percentage of time shown~~		~~Reference antenna radiation pattern~~
		~~99.7%~~	~~100%~~	
~~11.7-12.5 GHz in Region 1, 11.7-12.2 GHz and 12.5-12.75 GHz in Region 3~~	~~30~~ ~~60~~ ~~90~~	~~−172.3~~ ~~−183.3~~ ~~−186.8~~	~~−169.3~~ ~~−170.3~~ ~~−170.3~~	~~Recommendation ITU-R BO.1213~~

[1] Under this Section, reference patterns are to be used only for the calculation of interference from non-GSO FSS systems into GSO~~ FSS and~~ BSS systems.

[2] For BSS antenna diameters 180 cm, 240 cm and 300 cm, in addition to the single-entry limits shown in Table **S22-1D**, the following single-entry 100% of the time $EPFD_{down}$ limit also applies in the frequency band listed in Table **S22-1D**:

100% of the time $EPFD_{down}$ dB(W/(m^2 · 40 kHz))	**Latitude (North or South) (°)**
-160.0	$0 \leq \lvert latitude \rvert \leq 57.5$
-160.0 + 3.4 * (57.5 – $\lvert latitude \rvert$)/4	$57.5 \leq \lvert latitude \rvert \leq 63.75$
-165.3	$63.75 \leq \lvert latitude \rvert$

For BSS antenna diameter 240 cm, in addition to the above single-entry 100% of the time $EPFD_{down}$ limit, a -167 dB(W/(m^2 · 40 kHz)) single-entry 100% of the time operational $EPFD_{down}$ limit also applies to receive antennas located in Region 2, west of 140° W, north of 60° N, pointing toward

GSO BSS satellites at 91° W, 101° W, 110° W, 119° W and 148° W with elevation angles greater than 5°. [This limit is implemented during a transition period of [15] years.]*

MOD **S22.5~~D~~C** 2) The ~~aggregate~~equivalent power flux-density~~[2]~~[3], $EPFD_{up}$, produced at any point in the geostationary-satellite orbit by emissions from all the earth stations in a non-geostationary-satellite system in the fixed-satellite service in the frequency bands listed in Table S22-2, for all conditions and for all methods of modulation, shall not exceed the limits given in Table **S22-2** for the specified percentages of time. These limits relate to the equivalent power flux-density which would be obtained under free-space propagation conditions, into a reference antenna and in the reference bandwidth specified

---

* This transitional regime would be applicable only if the pfd limits in section 5c of Annex 1 to Appendix **S30** are sufficiently relaxed.

~~[3] **S22.5D.1** The aggregate power flux-density is defined as the sum of the power flux-densities produced at a point in the geostationary-satellite orbit by all the earth stations of a non-geostationary-satellite system. The aggregate power flux-density is computed by means of the following formula:~~

$$\cancel{apfd = 10 \cdot \log_{10} \left[\sum_{i=1}^{N_e} 10^{P_i/10} \cdot \frac{G_t(\theta_i)}{4 \pi d_i^2} \right]}$$

~~where:~~

~~N_e: number of earth stations in the non-geostationary-satellite system with an elevation angle greater than or equal to 0°, from which the point considered in the geostationary-satellite orbit is visible;~~

~~i: index of the earth station considered in the non-geostationary-satellite system;~~

~~P_i: RF power at the input of the transmitting antenna of the earth station considered in the non-geostationary-satellite system in dBW in the reference bandwidth;~~

~~θ_i: off-axis angle between the boresight of the earth station considered in the non-geostationary-satellite system and the direction of the point considered in the geostationary-satellite orbit;~~

~~$G_t(\theta_i)$: transmit antenna gain (as a ratio) of the earth station considered in the non-geostationary-satellite system in the direction of the point considered in the geostationary-satellite orbit;~~

~~d_i: distance in metres between the earth station considered in the non-geostationary-satellite system and the point considered in the geostationary-satellite orbit;~~

~~$apfd$: aggregate power flux-density in dB(W/m^2) in the reference bandwidth.~~

~~NOTE – Tables **S22-1** to **S22-4** and Nos. **S22.26** to **S22.29** contain provisional limits corresponding to an interference level caused by one non-geostationary fixed-satellite service system in the frequency bands to be applied in accordance with Resolutions **130 (WRC-97)** and **538 (WRC-97)**. These provisional limits are subject to review by ITU-R and are subject to confirmation by WRC-99. (WRC-97)~~

in Table **S22-2**, for all pointing directions towards the Earth's surface visible from any given location in the geostationary-satellite orbit.~~(WRC-97)~~

~~TABLE S22-2 (WRC-97)~~

~~Frequency band (GHz)~~	~~Aggregate pfd dB(W/m²/4 kHz)~~	~~Percentage of time during which aggregate pfd level may not be exceeded~~
~~17.3-18.1 in Regions 1 and 3 and 17.8-18.1 in Region 2~~	~~−163~~	~~100%~~

~~**S22.5E**~~ ~~3) The equivalent power flux-density[4], at any point on the Earth's surface visible from the geostationary-satellite orbit, produced by emissions from all the space stations of a non-geostationary-satellite system in the fixed-satellite service in the frequency bands listed in Table **S22-3**, including emissions from a reflecting satellite, for all conditions and for all methods of modulation, shall not exceed the limits given in Table **S22-3** for the given percentages of time. These limits relate to the equivalent power flux-density which would be obtained under free-space propagation conditions into all the reference antennas and in the reference bandwidths specified in Table **S22-3**, and for all pointing directions towards the geostationary-satellite orbit. (WRC-97)~~

TABLE S22-2

Limits to the $EPFD_{up}$ radiated by non-GSO FSS systems in certain frequency bands

Frequency band (GHz)	$EPFD_{up}$ dB(W/m²)	Percentage of time $EPFD_{up}$ level may not be exceeded	Reference bandwidth (kHz)	Reference antenna beamwidth and reference radiation pattern[2]
12.50-12.75 12.75-13.25 13.75-14.5	−160	100	40	4 degrees ITU-R S.672, Ls = -20[1]
*	−160	100	40	4 degrees ITU-R S.672, Ls = -20[1]
27.5-28.6	−162	100	40	1.55 degrees ITU-R S.672, Ls = -10[1]
29.5-30.0	−162	100	40	1.55 degrees ITU-R S.672, Ls = -10[1]

~~[4] **S22.5E.1** See No. **S22.5C.1**. (WRC-97)~~

[1] For the case of Ls=-10, the values a=1.83 and b=6.32 should be used in the equations in Annex 1 of Recommendation ITU-R S.672 for single-feed circular beams. In all cases of Ls, the parabolic main beam equation should start at zero.

* This $EPFD_{up}$ limit applies to the bands 17.3-18.1 GHz (Regions 1 and 3) and 17.8-18.1 GHz (Region 2). It is proposed that the above-mentioned limit be also applicable to the frequency band 17.3-17.8 GHz (Region 2), in order to protect BSS feeder links in Region 2 from non-GSO FSS uplinks in Regions 1 and 3. See also section 3.2.2.

MOD **S22.5~~G~~E** The limits given in Tables **S22-1**A to **S22-1D**~~and **S22-3**~~ may be exceeded on the territory of any country whose administration has so agreed~~. (WRC-97)~~

ADD **S22.5~~H~~F** The limits specified in No. **S22.5B** to **S22.5D** apply to non-GSO FSS systems for which complete coordination or notification information, as appropriate, has been received after 22 November 1997.

Reasons: Reflect the "*instructs the Radiocommunication Bureau*" in Resolutions 130 (WRC-97) and 538 (WRC-97), and *resolves* 2 of Resolution 130 (WRC-97). Review of the findings by the Bureau under "*instructs the Radiocommunication Bureau*" in Resolution 130 (WRC-97) and Resolution 538 (WRC-97) should be kept in an updated version of these resolutions to cover transitional aspects. It was noted that no notification was received prior to 22 November 1997 for non-GSO FSS systems (Earth-to-space) in the bands 17.3-18.1 GHz (Regions 1 and 3) and 17.8-18.1 GHz (Region 2).

ADD **S22.5~~I~~G** An administration operating a non-GSO FSS system which is in compliance with the limits in No. **S22.5B** to **S22.5D** (see also Resolution **WWW**) shall be considered as having fulfilled its obligations under No. **S22.2** with respect to any GSO network, irrespective of the dates of receipt by the Bureau of the complete coordination or notification information, as appropriate, for the non-GSO system and of the complete coordination information for the GSO network, provided that the $EPFD_{down}$ radiated by the non-GSO FSS system into any operating GSO FSS earth station does not exceed the operational limits given in Table **S22-4**A and **S22-4B**, when the gain of this earth station is equal to or greater than the corresponding value given in Table **S22-4**A and **S22-4B** for the corresponding orbital inclination of the GSO FSS satellite as given in Table **S22-4**A and **S22-4B**. Except as otherwise agreed between concerned administrations. ~~A~~an administration operating a non-GSO FSS system that is subject to the limits in No. **S22.5B** to **S22.5D** and which radiates $EPFD_{down}$ into any operating GSO FSS earth station at levels in excess of the operational limits given in Table **S22-4**A and **S22-4B**, when the gain of this earth station is equal to or greater than the corresponding value given in Table **S22-4**A and **S22-4B** for the corresponding orbital inclination of the GSO FSS satellite as given in Table **S22-4**A and **S22-4B**, shall be considered to be in violation of its obligations under No. **S22.2.**

Reasons: Reflect the *resolves* 4 and 1.4 of Resolutions 130 (WRC-97) and 538 (WRC-97), and the principles provided in section 3.1.2.1.4.2 c). Other additions to the provision correct the language, and make explicit the intention that any non-GSO FSS system that exceeds the validation or operational limits, as applicable, shall, except otherwise agreed between concerned administrations be deemed to be in violation of its obligations under No. S22.2.

TABLE S22-4A[1, 3]

Operational limits to the $EPFD_{down}$ radiated by non-GSO FSS systems in certain frequency bands

Frequency band (GHz)	$EPFD_{down}$ dB(W/m^2)	Percentage of time during which $EPFD_{down}$ may not be exceeded	Reference bandwidth (kHz)	Receive GSO earth station antenna diameter[2] (m)	Orbital inclination of GSO satellite (degrees)
10.7-11.7 in all Regions 11.7-12.2 in Region 2 12.2-12.5 in Region 3 and 12.5-12.75 in Regions 1 and 3 (prior to 31 December 2005)	-163 -166 -167.5 -169.5	100	40	3 6 9 ≥18	≤2.5
	-160 -163 -164.5 -166.5	100	40	3 6 9 ≥18	≤4.5
10.7-11.7 in all Regions 11.7-12.2 in Region 2 12.2-12.5 in Region 3 and 12.5-12.75 in Regions 1 and 3 (after 31 December 2005)	-161.25 -164 -165.5 -167.5	100	40	3 6 9 ≥18	≤2.5
	158.25 -161 -162.5 -164.5	100	40	3 6 9 ≥18	≤4.5

1 For certain receive earth stations, see also ADD **S9.7A** and ADD **S9.7B**.

2 Linear interpolation of EPFD levels in decibels should be performed for other intermediate antenna diameters.

3 In addition to the operational limits shown in Table **S22-4A**, the additional operational limits in Tables **S22-4A1** and **S22-4A2** apply to certain GSO FSS earth station antenna sizes in the frequency bands listed in Table **S22-4A**.

17.8–18.6	−150 −148	100 100	1 000 1 000	≥49 ≥49	≤2.5 ≥2.5 and ≤4.5

[1] For certain receive earth stations, see also ADD **S9.7A** and ADD **S9.7B**.

~~1~~2 The operational limit applies to non-GSO systems operating at altitudes of 7 000 km or above in order to protect GSO FSS systems employing adaptive coding.

ADD **S22.5H** In case of *force majeure*, telecommand and ranging carriers transmitted to non-geostationary satellites in the fixed-satellite service are not subject to the limits given in Table **S22-2**.

Reasons: Specific provision needed to cover emergency situations.

ANNEX 2 TO CHAPTER 3

EXAMPLE RESOLUTION WWW (WRC-2000)

Protection of GSO FSS and GSO BSS networks from the maximum aggregate equivalent power flux-density produced by multiple non-GSO FSS systems in frequency bands where EPFD limits have been adopted

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-97 has adopted, in Article **S22**, provisional EPFD limits to be met by non-GSO FSS systems in order to protect GSO FSS and GSO BSS networks in parts of the frequency range 10.7-30 GHz;

b) that WRC-2000 has revised these limits to ensure that they provide adequate protection to GSO systems without causing undue constraints to any of the systems and services sharing these frequency bands;

c) that Article **S22** includes single entry EPFD limits which apply to non-GSO FSS systems in these bands;

d) that these single-entry limits have been derived from aggregate equivalent power flux-density (EPFD) masks that are intended to protect GSO networks, assuming a maximum effective number of non-GSO FSS systems of 3.5;

e) that the aggregate interference caused by all co-frequency non-GSO FSS systems in these bands into GSO FSS systems should not exceed the maximum interference levels that are necessary to protect these GSO systems;

f) that WRC-97 decided, and WRC-2000 confirmed, that non-GSO FSS systems in these bands are to coordinate the use of these frequencies between themselves under the provisions of No. **S9.12** of the Radio Regulations;

g) that the orbital characteristics of such systems are likely to be inhomogeneous;

h) that as a result of this likely inhomogeneity, the aggregate EPFD levels from multiple non-GSO FSS systems are not directly related to the number of actual systems sharing a frequency band, and the number of such systems operating co-frequency is likely to be small~~,~~;

i) that the possible misapplication of single entry limits should be avoided,

recognizing

a) that non-GSO FSS systems are likely to need to implement interference mitigation techniques to share frequencies among themselves;

b) that because the use of such interference mitigation techniques will likely keep the number of non-GSO systems small, the aggregate interference caused by non-GSO FSS systems into GSO systems will also likely be small;

c) that notwithstanding *considering d)*, there may be instances where the aggregate interference from non-GSO systems could exceed the interference levels given in Annex 1;

d) that administrations operating GSO systems may wish to ensure that the aggregate EPFD produced by all operating co-frequency non-GSO FSS systems in the frequency bands referred to in *considering a)* above into GSO FSS and/or GSO BSS networks does not exceed the aggregate interference levels given in Annex 1,

resolves

1 that administrations operating or planning to operate non-GSO FSS systems in the frequency bands referred to in *considering a)* above, individually or in collaboration, take all possible steps, including by means of appropriate modifications to their systems if necessary, to ensure that the actual aggregate interference into GSO FSS and GSO BSS networks caused by such systems operating co-frequency in these frequency bands does not exceed the aggregate power levels shown in Annex 1;

2 that, in the event that the aggregate interference levels in Annex 1 are exceeded into an operational GSO earth station, administrations operating non-GSO FSS systems in these frequency bands shall expeditiously take all necessary measures to reduce the aggregate EPFD levels to those in Annex 1 or to reduce such interference to higher levels that are acceptable to the affected GSO administration,

requests ITU-R

1 to develop, as a matter of urgency, and complete, in time for consideration by the next WRC, a methodology for calculating the aggregate EPFD produced by all non-GSO FSS systems operating or planning to operate co-frequency in the frequency bands referred to in *considering a)* above into GSO FSS and GSO BSS networks and for comparing the calculated levels with the aggregate power levels shown in Annex 1;

2 to continue its studies on the accurate modelling of interference from non-GSO FSS systems into GSO FSS and GSO BSS networks in the frequency bands referred to in *considering a)* above in order to assist the administrations planning or operating non-GSO FSS systems in their efforts to limit the aggregate EPFD levels produced by their systems into GSO networks,

requests the Director of the Radiocommunication Bureau

to assist in the development of the methodology referred to in *requests ITU-R* 1 above.

ANNEX 1 (TO RESOLUTION WWW)

This Annex to Resolution WWW contains tables of interference levels concerning aggregate interference from multiple non-GSO FSS systems, which individually meet the Table **S22-1A** limits, into GSO FSS and GSO BSS systems.

Studies are continuing in order to avoid unnecessary entries in this Table and in order to provide maximum protection for the GSO FSS and GSO BSS.

1 Under this Section, reference patterns are to be used only for the calculation of interference from non-GSO FSS systems into GSO BSS systems.

2 For BSS antenna diameters 180 cm, 240 cm and 300 cm, in addition to the aggregate limit shown in Table **WWW-1D**, the following aggregate 100% of the time $EPFD_{down}$ limit also applies:

100% of the time $EPFD_{down}$ dB(W/(m^2 · 40 kHz))	**Latitude (North or South) (°)**
-160.0	0 ≤ |latitude| ≤ 57.5
-160.0 + 3.4 * (57.5 – |latitude|)/4	57.5 ≤ |latitude| ≤ 63.75
-165.3	63.75 ≤ |latitude|

For BSS antenna diameter 240 cm, in addition to the above aggregate 100% of the time $EPFD_{down}$ limit, a -167 dB(W/(m^2 · 40 kHz)) aggregate 100% of the time operational $EPFD_{down}$ limit also applies to receive antennas located in Region 2, west of 140° W, north of 60° N, pointing toward GSO BSS satellites at 91° W, 101° W, 110° W, 119° W and 148° W with elevation angles greater than 5°. [This limit is implemented during a transition period of [15] years.]*

* This transitional regime would be applicable only if the pfd limits in section 5c of Annex 1 to Appendix **S30** are sufficiently relaxed.

ANNEX 3 TO CHAPTER 3

Example of possible modifications for coordination between non-GSO FSS transmitting space stations and GSO receive earth stations with very large antennas

This Annex contains example of regulatory and procedural text for coordination between non-GSO FSS transmitting space stations and GSO receive earth stations with very large antennas, including additions and/or modifications to Articles **S9, S11** and **S22** and Appendices **S4** and **S5**.

ARTICLE S9

Sub-Section IIA - Requirement and request for coordination

ADD S9.7A *a1)* [12, 13] for a specific earth station within a geostationary-satellite network in the fixed-satellite service in certain frequency bands in respect of a non-geostationary-satellite system in the fixed-satellite service;

ADD S9.7B *a2)* [12, 13] for a non-geostationary-satellite system in the fixed-satellite service in certain frequency bands in respect of a specific earth station within a geostationary-satellite network in the fixed-satellite service;

ADD S9.7.A.1 and S9.7.B.1 [12] The coordination of a specific earth station under **S9.7A** or **S9.7B** shall remain within the authority of the administration having this station located on its territory.

ADD S9.7.A.2 and S9.7.B.2 [13] Coordination information relating to a specific earth station received by the Bureau prior to [date ~~TBD~~to be established by WRC-2000] is considered as complete **S9.7A** or **S9.7B** information from the date of receipt of complete information of the associated satellite network under **S9.7** provided that the characteristics of the specific earth stations are within the parameters of any typical earth station included in the GSO FSS network coordination request.

MOD S9.8.1 and S9.9.1 [~~12~~14] Application of this provision with respect to Articles **6** and **7** of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.

Reasons: GSO FSS earth stations with very large antennas may not be adequately protected by the $EPFD_{down}$ limits contained in Table MOD **S22-1** and case-by-case coordination of systems operating co-frequency, co-directional links in the space-to-Earth direction would then be required. The proposed ADD **S9.7A** and ADD **S9.7B** would require coordination between non-GSO FSS transmit satellites and GSO FSS receive earth stations with very large antennas. By referring to coordination provisions under **S9.7A** and **S9.7B**, the request for coordination would be sent by the requesting administration to the Bureau under **S9.30**. The Bureau would act under **S9.34** to identify administrations with which coordination may need to be effected and publish the information in the Weekly Circular. Since coordination between a non-GSO FSS space station and very large GSO FSS earth stations is a new type of coordination that does not currently exist in Article **S9**, it is necessary to add two new entry points in Article **S9**:

- One entry point to enable the non-GSO space station administration to request coordination with administrations having specific very large earth station antennas located on their territory.
- Another entry point to enable the reciprocal coordination to take place, i.e. the possibility for an administration planning to implement a specific very large GSO earth station stations located on their territory to request coordination with administrations having non-GSO FSS transmit space.

TABLE **S22-1 (MOD)**[1]

TABLE **S22-4 (MOD)**[1]

ADD [1] For certain receive earth stations, see also ADD **S9.7A** and ADD **S9.7B**.

Reasons: Case-by-case coordination is required by the proposed modifications in ADD **S9.7A** and ADD **S9.7B**.

ARTICLE S11

Section II – Examination of notices and recording of frequency assignments in the Master Register

MOD S11.32A *c)* with respect to the probability of harmful interference that may be caused to or by assignments recorded with a favourable finding under Nos. **S11.36** and **S11.37** or **S11.38**, or recorded in application of No. **S11.41**, or published under Nos. **S9.38** or **S9.58** but not yet notified, as appropriate, for those cases for which the notifying administration states that the procedure for coordination under Nos. **S9.7**, **S9.7A or S9.7B** could not be successfully completed (see also No. **S9.65**);[10] or

MOD S11.32A.1 [10] The examination of such notices with respect to any other frequency assignment for which a request for coordination under Nos. **S9.7**, **S9.7A or S9.7B** has been published under No. **S9.38** but not yet notified shall be effected by the Bureau in the order of their publication under the same number using the most recent information available.

Reasons: The insertion of a coordination trigger related to $EPFD_{down}$ level radiated by the non-GSO FSS system into the earth station employing the very large antenna considered when this earth station is pointed to the wanted GSO satellite provides a mechanism to examine the notice with respect to the probability of harmful interference that may be caused to or by above-listed assignments, and therefore S11.38 and S11.41 are applicable.

MOD TO APPENDIX S4

ANNEX 2B (TO APPENDIX S4)

Table of characteristics to be submitted for space and radio astronomy services

The required characteristics for coordinating specific very large GSO earth stations with non-GSO FSS transmit space stations could be items for "Notification or coordination of a GSO network (including Appendix **S30B**)" or "Notification or coordination of an earth station."

(The modifications in either column two or column three need to be incorporated into the full table.)

C – Characteristics to be provided for each group of frequency assignments for a satellite antenna beam or an earth station antenna

X Mandatory information.

O Optional information.

C This information need only be furnished when it has been used as a basis to effect coordination with another administration.

~~##~~9 Information mandatory for coordination under No. ADD **S9.7A**.

NOTE – Additional characteristics to be provided may include A.4.c, A.1.e.1, A.1.e.2, C.4, B.5 and C.5.b. As a result of decisions that may be made at WRC-2000, these additional characteristics may replace C.10.a, C.10.b, C.10.c.1, C.10.c.2 and C.10.c.5 in the notification or coordination of an earth station column.

Reasons: This is consequential to ADD **S9.7A** and ADD **S9.7B**. Administrations will need to submit specific earth station information for earth stations associated with geostationary-satellite networks in the fixed-satellite service meeting the conditions in the proposed addition to Appendix **S5**.

MOD (to RR App. S4)

D – Overall link characteristics

(The modifications in either column two or column three need to be incorporated into the full table.)

Items in Appendix	Notification or coordination of a geostationary satellite network (including Appendix S30B)	Notification or coordination of an earth station

[9] Information mandatory for coordination under No. ADD **S9.7A**.

Reasons: This is consequential to ADD **S9.7A** and ADD **S9.7B** and will be required when simple frequency-changing transponders are used on the space station.

ADD

APPENDIX S5

TABLE **S5-1** *(continued)*

Reference of Article S9	Case	Frequency bands (and Region) of the service for which coordination is sought	Threshold/condition	Calculation method	Remarks
No. **S9.7A** GSO earth station/ non-GSO system	A specific earth station in a geostationary-satellite network in the fixed-satellite service in respect of a non-geostationary-satellite system in the fixed-satellite service.	The following frequency bands: 10.7-11.7 GHz (space-to-Earth), 11.7-12.2 GHz (space-to-Earth) in Region 2, 12.2-12.75 GHz (space-to-Earth) in Region 3, 12.5-12.75 GHz (space-to-Earth) in Region 1, 17.8-18.6 GHz (space-to-Earth), and 19.7-20.2 GHz (space-to-Earth)	Conditions: i) the frequency bands overlap; and ii) the satellite network using the geostationary-satellite orbit has specific receive earth stations and meets all of the following conditions: a) Earth station antenna maximum isotropic gain greater than or equal to 64 dBi for the frequency bands 10.7-12.75 GHz or 68 dBi for the frequency bands 17.8-18.6 GHz and 19.7-20.2 GHz; b) G/T_1 of 44 dB/K or higher; c) space station emission bandwidth of 250 MHz or higher for the frequency bands 10.7-12.75 GHz or 800 MHz or higher for the frequency bands 17.8-18.6 GHz and 19.7-20.2 GHz; iii) the $EPFD_{down}$ from the satellite system using the non-geostationary orbit exceeds:	i) compare frequency bands; ii) use the maximum antenna gain of the specific receive earth station (Appendix **S4** C.10 *c)* 2)), the lowest equivalent satellite link noise temperature (Appendix **S4** C.10 *c)* 5)), and the space station emission bandwidth (Appendix **S4** C.7 *a)*) in the geostationary-satellite network as given in Appendix **S4** data; and iii) use the $EPFD_{down}$ radiated by the non-GSO FSS system into the earth station employing the very large antenna when this antenna is pointed towards the wanted GSO satellite.	The threshold/ condition for coordination do not apply to typical receive earth stations operating in satellite networks using the geostationary-satellite orbit.

			a) either –174.5 dB(W/(m^2 · 40 kHz)) for any percentage of time or [x] dB(W/(m^2 · 40 kHz)) for [y]% of the time in the frequency band 10.7-12.75 GHz; b) either –151 dB(W/(m^2 · MHz)) for any percentage of time or [x'] dB(W/(m^2 · MHz)) for [y']% of the time in the frequency bands 17.8-18.6 GHz or 19.7-20.2 GHz.		
No. **S9.7B** non-GSO system/ GSO earth station/	A non-geostationary-satellite system in the fixed-satellite service in respect of a specific earth station in a geostationary-satellite network in the fixed-satellite service.	The following frequency bands: 10.7-11.7 GHz (space-to-Earth), 11.7-12.2 GHz (space-to-Earth) in Region 2, 12.2-12.75 GHz (space-to-Earth) in Region 3, 12.5-12.75 GHz (space-to-Earth) in Region 1, 17.8-18.6 GHz (space-to-Earth), and 19.7-20.2 GHz (space-to-Earth)	Conditions: i) the frequency bands overlap; and ii) the satellite network using the geostationary-satellite orbit has specific receive earth stations and meets all of the following conditions: a) Earth station antenna maximum isotropic gain greater than or equal to 64 dBi for the frequency bands 10.7-12.75 GHz or 68 dBi for the frequency bands 17.8-18.6 GHz and 19.7-20.2 GHz; b) G/T_1 of 44 dB/K or higher;	i) compare frequency bands; ii) use the maximum antenna gain of the specific receive earth station (Appendix **S4** C.10 *c)* 2)), the lowest equivalent satellite link noise temperature (Appendix **S4** C.10 *c)* 5)), and the space station emission bandwidth (Appendix S4 C.7 *a)*) in the geostationary-satellite network as given in Appendix **S4** data; and	The threshold/ condition for coordination do not apply to typical receive earth stations operating in satellite networks using the geostationary-satellite orbit.

			c) space station emission bandwidth of 250 MHz or higher for the frequency bands 10.7-12.75 GHz or 800 MHz or higher for the frequency bands 17.8-18.6 GHz and 19.7-20.2 GHz; iii)the $EPFD_{down}$ from the satellite system using the non-geostationary orbit exceeds: a) either –174.5 $dB(W/(m^2 \cdot 40\ kHz))$ for any percentage of time or [x] $dB(W/(m^2 \cdot 40\ kHz))$ for [y]% of the time in the frequency band 10.7-12.75 GHz b) either –151 $dB(W/(m^2 \cdot MHz))$ for any percentage of time or [x'] $dB(W/(m^2 \cdot MHz))$ for [y']% of the time in the frequency bands 17.8-18.6 GHz or 19.7-20.2 GHz.	iii) use the $EPFD_{down}$ radiated by the non-GSO FSS system into the earth station employing the very large antenna when this antenna is pointed towards the wanted GSO satellite.	

Reasons: This is consequential to ADD **S9.7A** and **S9.7B**.

ANNEX 4 TO CHAPTER 3

(relative to the current Radio Regulations)

Examples of modifications to TABLE **S21-4** *(continued)*

Frequency band	Service*	Limit in dB(W/m²) for angle of arrival (δ) above the horizontal plane			Reference bandwidth
		0°-5°	**5°-25°**	**25°-90°**

MOD

12 **S21.16.6** ~~These values shall apply provisionally only to emissions of space stations on non-geostationary satellites in networks operating with a large number of satellites, that is systems operating with more than 100 satellites (see Resolution **131 (WRC-97)**). (WRC-97)~~

The function X is defined as a function of the number, N, of satellites in the non-GSO FSS constellation as follows:

– for $N \leq 50$ $X = 0$ (dB)

– for $50 < N \leq 288$ $X = \frac{5}{119}(N - 50)$ (dB)

– for $N > 288$ $X = \frac{1}{69}(N + 402)$ (dB)

In the band 18.8-19.3 GHz, these limits apply to emissions of a space station on a non-geostationary FSS satellite for which complete coordination or notification information, as appropriate, has been received by the Radiocommunication Bureau after 17 November 1995, and which was not operational by that date.

ADD[aa]
S21.16.*6bis* These limits apply to emissions of a space station on a meteorological-satellite and on a geostationary FSS satellite. These limits also apply to emissions of a space station on a non-geostationary FSS satellite in the bands 18.8-19.3 GHz for which complete coordination or notification information has been received by the Radiocommunication Bureau by 17 November 1995, or are in operation by that date~~(WRC-2000)~~.

Reasons: The above regulatory text reflects the date-specific provisions currently in Resolution **131 (WRC-97)**.

Reasons: The above regulatory text maintains the original limits for non-GSO FSS systems in the band 18.8-19.3 GHz that were notified or operational prior to the end of WRC-95 per the decision in Resolution 131 (WRC-97). In the band 17.7-18.8 GHz, the new limits would apply to all non-GSO systems irrespective of the date of receipt of information or date of bringing into operation.

ANNEX 5 TO CHAPTER 3

Example of possible modifications to Resolutions 130 and 538

RESOLUTION 130 (WRC-~~97~~2000)

Use of non-geostationary systems in the fixed-satellite service in certain frequency bands

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that the International Telecommunication Union has, among its purposes, "to promote the extension of the benefit of the new telecommunication technologies to all the world's inhabitants" (No. 6 of the Constitution of the International Telecommunication Union (Geneva, 1992));

b) that it is desirable, in this respect, to promote systems capable of providing universal service;

c) that new telecommunication services need advanced and reliable networks permitting high-capacity communications;

d) the need to encourage the development and implementation of new technologies;

e) that systems based on the use of new technologies associated with both geostationary (GSO) and non-geostationary (non-GSO) satellite constellations are capable of providing the most isolated regions of the world with high-capacity and low-cost means of communication;

f) that there should be equitable access to the radio-frequency spectrum and orbital resources in a mutually acceptable manner that allows for new entrants in the provision of services;

g) that all Member States would benefit from the implementation of proposed systems in the allocated spectrum and from avoidance of monopolization or exclusive use of an allocation by a single system;

h) that the operation of such systems requires a suitable amount of spectrum in appropriate frequency bands;

i) that decisions on this matter should permit the operation of as many systems as possible;

j) that~~, in spite of the urgency attached to the development of such systems,~~ technical, operational and regulatory issues should be studied in order to achieve the most efficient use of the spectrum that may be available for these systems;

k) that there is a need for the provision of services on a competitive basis between GSO fixed-satellite service (FSS) and non-GSO FSS systems as well as between non-GSO FSS and non-GSO FSS systems;

l) that the Radio Regulations must be sufficiently flexible to accommodate the introduction and implementation of innovative technologies as they evolve, and allow the further development and implementation of any proposed system in conformity with their provisions,

considering further

a) that the ITU-R has conducted ~~further~~ technical, operational and regulatory studies ~~are required~~ in order to determine ~~further~~ the conditions under which sharing of the frequency bands 10-30 GHz which are allocated to the FSS and where ~~Resolution **46 (Rev.WRC-97)**~~No. **S9.11A** does not apply is feasible between GSO and non-GSO systems, between non-GSO systems and between non-GSO and terrestrial systems and other space systems;

~~*b)* that it is likely that non-GSO FSS systems communicated to the Radiocommunication Bureau will not be brought into use before the WRC-99;~~

~~*c*~~*b)* that the diverging interpretations arising from No. **S22.2** result in an ambiguous regulatory status for both existing and future GSO and non-GSO systems in the FSS in the bands where this provision applies, with consequential risks for both types of systems;

~~*d*~~*c)* that the harmonious development of non-GSO and GSO systems in the FSS requires that these ambiguities be resolved with no further delay in all bands subject to this provision;

~~*e*~~*d)* that in resolving these ambiguities in the bands referred to in *resolves* 1 below, the GSO arc must be protected to ensure continued use of existing FSS systems and the development of new GSO technologies and systems in both non-planned bands and bands where plans exist;

~~*f*~~*e)* that these ambiguities can ~~may~~ be resolved in certain frequency bands by adopting power flux-density (pfd) limits which ~~would~~ apply to non-GSO FSS systems to protect GSO FSS systems, and by including in Article **S22** limits on the power radiated by non-GSO FSS systems in order adequately to protect GSO FSS systems in the frequency bands and sharing situations where ~~Resolution **46 (Rev.WRC-97)**~~ No. **S9.11A** does not apply;

~~*g*~~*f)* that in certain frequency bands which are currently used or planned to be used extensively by GSO FSS systems, ~~provisional~~ power flux-density limits applicable to non-GSO FSS systems have been developed;

~~h~~g) that non-GSO FSS systems have been proposed in some of these bands which could meet these limits and would not require specific protection from existing and future GSO FSS systems, provided that minimum constraints are applied to GSO FSS systems, such as off-axis earth station e.i.r.p. limits;

~~i~~h) that in the bands where the limits referred to in *considering further ~~e~~f), ~~f~~g)* and *~~g~~h)* ~~would~~ apply, there is ~~would be~~ no need for a coordination procedure between non-GSO FSS and GSO systems, with the exception of coordination between earth stations operating in opposite directions of transmission and coordination with earth stations using very large antennas;

~~j~~i) that there ~~would be~~ is a need for a coordination procedure between non-GSO systems in the FSS and between non-GSO FSS systems and non-GSO systems in other services and for specific sharing criteria associated with this procedure, taking into consideration various types of non-GSO systems, including those in highly elliptical orbits;

~~k~~j) the need to protect other co-primary services having allocations in the frequency bands referred to in *considering further a)* above and the need to assess further the sharing conditions between non-GSO FSS systems and these services;

~~l~~k) that there is a need for further studies on sharing conditions in frequency bands other than the 10-30 GHz frequency bands, where ~~Resolution 46 (Rev.WRC-97)~~No. S9.11A does not apply and Article S22 does not include limits for non-GSO FSS systems, ~~may also be necessary~~ on the basis of the requirements that may emerge,

noting

1 that information relating to GSO and non-GSO systems in the FSS in the 10-30 GHz bands has been communicated to the Bureau;

2 that some of these systems are in operation and others will be operated in the near future and, consequently, difficulties may be experienced in modifying their characteristics;

3 the need to protect existing and future terrestrial and space services and systems;

4 that No. **S22.2** is an operational provision which is to be applied between administrations, and does not require any specific action or finding by the Bureau,

recognizing

that the geostationary-satellite orbit and its associated spectrum are a uniquely valuable resource and that equitable access to this resource needs to be protected for all countries in the world,

resolves

1 that, as of 22 November 1997, in the frequency bands specified in Tables **S22-1A, S22-1B, S22-1C** and **S22-2** of Article **S22**, ~~and in Tables 1 and 2 in Annex 1 to this Resolution,~~ non-GSO FSS systems ~~shall apply the procedures of Section I of Article S9, Nos. S9.17 and S9.17A/Sections I and III of Article 11 and the procedures of Article S11/13, and the non-GSO FSS systems~~ for which complete notification or coordination information, as appropriate, has been received by the Bureau after 21 November 1997 shall be subject to the ~~provisional~~ power limits in Article **S22**, as revised by this Conference ~~and in Annex 1 to this Resolution~~;

CPM Comment: WRC-2000 may be in a position to determine that resolves 1 is no longer required after WRC-2000 because:

- *Articles 11 and 13 have been suppressed.*
- *Sections I and III of **S9**, **S9.17** and **S9.17A** apply to all non-GSO FSS not subject to **S9.11A**.*

- *The limits in Article **S22** are enabled by the fact they appear in Article **S22** itself.*

~~2 that these limits shall be applied provisionally until the end of WRC-99, and that non-GSO FSS systems for which complete notification information has been received by the Bureau after 21 November 1997 shall be subject to the power limits in Article **S22**, as revised, if appropriate, by WRC-99;~~

CPM Comment: WRC-2000 may be in a position to determine that resolves 2, a transitional measure until WRC-2000 is no longer required after WRC-2000.

~~3 that, as of 22 November 1997, in applying No. **S22.2**, administrations may consider these provisional power limits as corresponding to permissible levels of interference from a non-GSO system into a GSO system, irrespective of the dates of receipt by the Bureau of the complete notification information relating for the non-GSO system and of the complete coordination information for the GSO network;~~

CPM Comment: WRC-2000 may be in a position to determine that resolves 3, a transitional measure until WRC-2000 is no longer required after WRC-2000.

~~4 that, as of the end of WRC-99, an administration operating a non-GSO FSS system which is in compliance with the limits in Article **S22**, as revised, if appropriate, by WRC-99, shall be considered as having fulfilled its obligations under No. **S22.2** with respect to any GSO network, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO system and of the complete coordination information for the GSO network;~~

*CPM Comment: If WRC-2000 elects to move this fundamental provision to Article **S22**, resolves 4 may be able to be suppressed.*

~~5 that, as of the end of WRC-99, in the frequency bands specified in No. **S22.29** and § 2.4 of Annex 1 to this Resolution, GSO FSS systems for which complete coordination information has been received by the Bureau after the end of WRC-99 shall be subject to the limits in Article **S22** and in § 2.1, 2.2 and 2.3 of Annex 1 to this Resolution, as revised, if appropriate, by WRC-99;~~

*CPM Comment: WRC-2000 may be in a position to determine that resolves 5 is no longer required after WRC-2000; the limits in Article **S22** are enabled by the fact they appear in Article **S22** itself.*

~~6 that, as of 22 November 1997, in the frequency bands specified in No. **S22.29** and Tables 1 and 2 of Annex 1 to this Resolution, non-GSO systems shall not claim protection from GSO networks in the FSS operating in accordance with the Radio Regulations, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO FSS systems and of the complete coordination information for the GSO networks;~~

OR

6 that, as of 22 November 1997, in the frequency bands specified in No. **S22.29** and Tables **S22-1A, S22-1B, S22-1C** and **S22-2** ~~Tables 1 and 2 of Annex 1 to this Resolution~~, non-GSO systems shall not claim protection from GSO networks in the FSS operating in accordance with the Radio Regulations, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO FSS systems and of the complete coordination information for the GSO networks;

*CPM Comment: If WRC-2000 determines that resolves 6 may be suppressed, WRC-2000 may also need to determine whether, in view of considering further g) above, retaining resolves 6 in Resolution **130** or Article **S5** would require the establishment of minimum constraints on GSO FSS systems (such as earth station off-axis power limits). If, in the alternative, WRC-2000 determines that resolves 6 is an essential measure that is not dependent on the establishment of minimum* *constraints on GSO FSS systems, the resolves (suitably modified) will need either to be reflected in appropriate fashion in footnotes of Article **S5** or retained in Resolution **130 (MOD WRC-2000)**.*

~~6.1 that, between 22 November 1997 and the end of WRC-99, if an administration operating or bringing into use a GSO FSS system before the end of WRC-99 considers that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system, then:~~

~~6.1.1 the administration operating the GSO system shall send to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based,~~

~~6.1.2 in the bands from 10.7 GHz to 14.5 GHz, the administration operating the non-GSO FSS system shall resolve the difficulties,~~

~~6.1.3 in the bands 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space) and 29.5-30.0 GHz (Earth-to-space), the administrations concerned shall make every possible effort to resolve the difficulties by means of mutually acceptable adjustments to their networks;~~

OR

6.1 that, between 22 November 1997 and the end of WRC-2000~~99~~, if an administration operating or bringing into use a GSO FSS system before the end of WRC-2000~~99~~ considers that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system, then:

6.1.1 the administration operating the GSO system shall send to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based,

6.1.2 in the bands from 10.7 GHz to 14.5 GHz, the administration operating the non-GSO FSS system shall resolve the difficulties,

6.1.3 in the bands 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space) and 29.5-30.0 GHz (Earth-to-space), the administrations concerned shall make every possible effort to resolve the difficulties by means of mutually acceptable adjustments to their networks;

CPM Comment: If WRC-2000 determines that resolves 6.1, 6.1.1, 6.1.2, and 6.1.3 are transitional measures until WRC-2000, these provisions may be able to be suppressed. If, however, administrations have invoked the provisions of resolves 6.1, WRC-2000, in addressing this situation, may determine that it is necessary to retain or modify resolves 6.1, 6.1.1, 6.1.2, and 6.1.3.

~~7 that, if an administration bringing into use a GSO FSS system after the end of WRC-99 considers that a non-GSO FSS system proposed by another administration and which complies with the limits in Article **S22**, as revised, if appropriate, by WRC-99, might cause unacceptable interference into its GSO system, the administrations concerned shall make every possible effort to resolve the difficulties by means of mutually acceptable adjustments to their networks;~~

*CPM Comment: If WRC-2000 determines that resolves 7 is adequately covered by RR No. **S9.4**, resolves 7 may be able to be suppressed. Because an administration bringing a GSO FSS system into use may not be in a position to know if the non-GSO FSS system proposed by the other administration complies with the applicable WRC-2000 power limits under the time-table established in RR No. **S9.3**, WRC-2000 may find it appropriate to retain a suitably modified resolves 7.*

~~8 that, as of 22 November 1997, non-GSO systems in the FSS in the frequency bands referred to in *resolves* 1 above, shall, for coordination with other non-GSO FSS systems, be subject to application of the provisions of § 2.1 of Section II of Resolution 46 (Rev.WRC-97)/No. S9.12;~~

*CPM Comment: If WRC-2000 elects to move this fundamental provision into footnotes of Article **S5**, resolves 8 may be suppressed.*

requests ITU-R

1~~1~~ taking into account *considering further a)*, to conduct, as a matter of urgency, and complete, in time for consideration by WRC-~~99~~02/03~~:~~, ~~1.3~~ the studies relating to the sharing criteria to be applied during the coordination between non-GSO FSS systems and the need for coordination between terrestrial services and non-GSO systems in the FSS and in other space services, with a view to promoting efficient use of spectrum/orbit resources and equitable access to these resources by all countries;

~~1.1 the appropriate technical, operational and regulatory studies to review the regulatory conditions relating to the coexistence of non-GSO and GSO systems in the FSS, in order to ensure that they do not impose undue constraints on the development of non-GSO and GSO FSS systems;~~

~~1.2 the development of a methodology for calculating the power levels produced by non-GSO FSS systems and the compliance of these levels with the limits referred to in *resolves* 1 and 2 above;~~

2~~1~~ taking into account *considering further ~~l~~k)*~~, to undertake the development~~ to conduct the appropriate technical, operational and regulatory studies towards the possible adoption of power limits or other frequency sharing mechanisms among GSO, non-GSO and terrestrial systems in the frequency bands other than those referred to in *resolves* 1 above and where non-GSO FSS systems are likely to be implemented and GSO systems are used or expected to be used extensively,

CPM Comment: WRC-2000 may find it advisable to repeat requests 1.1 (with conforming modifications) following requests 2, as a new requests 3.

instructs the Radiocommunication Bureau

as of the end of WRC-~~99~~2000, to review and, if appropriate, revise, any finding previously made on the compliance with the limits contained in Article **S22** of a non-GSO FSS system for which complete notification or coordination information, as appropriate, has been received between 22 November 1997 and the end of WRC-2000~~99~~. This review shall be based on the values in Article **S22**, as revised~~, if appropriate,~~ by WRC-~~99~~2000.

~~1 See Annex 2 for further details concerning specific aspects of these studies in relation to frequency sharing between systems in the non-GSO FSS and the GSO FSS.~~

SUP ~~ANNEX 1 TO RESOLUTION 130 (WRC-97)~~

~~**Provisional limits**~~

SUP ~~ANNEX 2 TO RESOLUTION 130 (WRC-97)~~

~~**ITU-R studies on frequency sharing between non-GSO FSS and GSO FSS**~~

RESOLUTION 538 (WRC-~~97~~2000)

Use of the frequency bands covered by Appendices S30/30 and S30A/30A by non-geostationary-satellite systems in the fixed-satellite service

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that provisional limits have been revised ~~established~~ and included in Article **S22** ~~and in the Annex to this Resolution~~ to ensure that the interference caused by non-geostationary-satellite (non-GSO) systems in the fixed-satellite service (FSS) into assignments operated in conformity with the Appendices **S30** and **S30A** Plans is maintained within negligible levels;

b) that the integrity of the above-mentioned Plans and their future modifications is to be ensured;

c) that non-GSO systems should not be entered into those Plans and therefore should not apply the procedures associated with the Plans and should not be protected by those procedures;

d) that WRC-97 ~~this Conference~~ has decided to introduce in Article **S5** a new allocation to the FSS in the frequency bands 11.7-12.5 GHz in Region 1, 12.2-12.7 GHz in Region 2 and 11.7-12.2 GHz in Region 3, limited to non-GSO FSS systems,

resolves

~~1~~

~~1.~~1 that, as of 22 November 1997, a non-GSO FSS system operating in the frequency bands covered by Appendices **S30** and **S30A** shall comply with the ~~provisional limits specified in Article S22 and in the Annex to this Resolution; 1.2 that such a system shall, as of the end WRC-99, comply with the~~ limits specified in Article **S22**, as revised~~, if appropriate,~~ by WRC-~~99~~2000, irrespective of the date of receipt of the complete notification information relating to the non-GSO FSS system;

~~1.3 that as of 22 November 1997, in applying No. **S22.2**, administrations may consider these provisional power limits as corresponding to permissible levels of interference from a non-GSO system into a GSO system, irrespective of the dates of receipt by the Radiocommunication Bureau of the complete notification information for the non-GSO system and for the GSO network;~~

CPM Comment: WRC-2000 may be in a position to determine that resolves 1.3, a transitional measure until WRC-2000 is no longer required after WRC-2000.

~~1.4 that as of the end of WRC-99, an administration operating a non-GSO FSS system in the band 17.8-18.1 GHz (space-to-Earth) which is in compliance with the limits appearing in Article **S22** as revised, if appropriate, by WRC-99, shall be considered as having fulfilled its obligations under No. **S22.2** with respect to any GSO network operating in the Earth-to-space direction, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO system and of the complete coordination or notification information, as appropriate, for the GSO network;~~

*CPM Comment: If WRC-2000 elects to move this fundamental provision to Article **S22**, resolves 1.4 may be able to be suppressed. It may also be appropriate to extend this provision to all the bands subject to Resolution **538 (WRC-97)**, since RR No. **S22.2** now applies to both GSO FSS and GSO BSS protection from non-GSO systems.*

~~1.5 that between 22 November 1997 and the end of WRC-99, if an administration operating or bringing into use a GSO system before the end of WRC-99 considers that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system, then:~~

- ~~the administration operating the GSO system shall send to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based;~~
- ~~the administration operating the non-GSO FSS system shall resolve the difficulties, taking into account especially degradation of picture and sound quality or signal availability with regard to GSO systems in operation;~~

OR

~~1.5~~2 that between 22 November 1997 and the end of WRC-2000~~99~~, if an administration operating or bringing into use a GSO system before the end of WRC-2000~~99~~ considers that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system, then:

– the administration operating the GSO system shall send to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based;

– the administration operating the non-GSO FSS system shall resolve the difficulties, taking into account especially degradation of picture and sound quality or signal availability with regard to GSO systems in operation;

CPM Comment: If WRC-2000 determines that resolves 1.5 is a transitional measure until WRC-2000, this provision may be able to be suppressed. If, however, administrations have invoked the provisions of resolves 1.5, WRC-2000, in addressing this situation, may determine that it is necessary to retain or modify resolves 1.5.

~~1.6 that, as of 22 November 1997, a non-GSO FSS system operating in the frequency bands covered by Appendices **S30** and **S30A** shall apply the procedures of Section I of Article **S9**, and Nos. **S9.17** and **S9.17A** Sections I and III of Article **11**, and the procedures of Article **S11/13**;~~

CPM Comment: WRC-2000 may be in a position to determine that resolves 1.6 is no longer required after WRC-2000 because:

- *Articles 11 and 13 have been suppressed; and*
- *Sections I and III of **S9**, **S9.17** and **S9.17A** apply to all non-GSO FSS not subject to **S9.11A**.*

~~1.7 that, as of 22 November 1997, such a system shall be subject, for the coordination with non-GSO systems, to the application of the provisions of § 2.1 of Section II of Resolution **46 (Rev.WRC-97)**/No. **S9.12**;~~

CPM Comment: If WRC-2000 elects to move this fundamental provision into footnotes of Article S5, resolves 1.7 may be suppressed.

~~1.8 that, as of 22 November 1997, such a system shall apply, using an equivalent power flux-density threshold of –185.3 dB(W/m²/4 kHz) for 99.7% of the time, calculated with the reference 90 cm diameter antenna pattern provided in Annex 5 of Appendix **S30** for Regions 1 and 3, the provisions of No. **S9.8**/Article 7 of Appendix **S30** with respect to assignments which appear in Article 11 of Appendix **S30** with the symbols AE or PE;~~

*CPM Comment: WRC-2000 may be in a position to determine that resolves 1.8 is no longer required after WRC-2000 because this provision was intended to provide the protection of 90 cm antennas corresponding to the "old" assignments in the pre-1997 Appendix **30** Plan in Regions 1 and 3. Since the antenna diagram used to protect BSS antennas is now expected to be the same for all Regions and diameters, this specific provision is no longer required.*

~~2 that non-GSO FSS systems in the frequency bands referred to in *resolves* 1 above shall not be operated before the end of WRC-99,~~

CPM Comment: WRC-2000 may be in a position to determine that resolves 2, a transitional measure until WRC-2000, is no longer required after WRC-2000.

requests ITU-R

SUP a), b), c) and d)

*CPM Comment: Alternative to requests ITU-R, WRC-2000 may consider extending the scope of ITU-R studies under the Resolution to other bands allocated to the BSS and associated feeder links if required. For these studies, frequency overlap with bands in Resolution **130 (WRC-2000)** should be avoided.*

instructs the Radiocommunication Bureau

as of the end of WRC-~~99~~2000, to review and, if appropriate, revise, any finding previously made on the compliance with the limits contained in Article **S22** of a non-GSO FSS system for which complete coordination and notification information, as appropriate, has been received between 22 November 1997 and the end of WRC-2000~~99~~. This review shall be based on the values in Article **S22**, as revised~~, if appropriate,~~ by WRC-2000~~99~~.

SUP ~~ANNEX TO RESOLUTION 538 (WRC-97)~~

~~**Provisional limits**~~

ANNEX 6 TO CHAPTER 3

Example of possible modifications to Footnotes in Article S5 (Resolutions 130 and 538)

REGULATORY/PROCEDURAL TEXT FOR WRC-2000 AGENDA ITEM 1.13

Section 3.1.2.4.1 notes that as a result of the need to modify Resolutions **130** and **538**, consequential changes will be required to footnotes in Article **S5** that make reference to these Resolutions.

1 Example modifications to footnotes based on Resolution 130 (WRC-97) and Resolution 538 (WRC-97)

Option 1A Example modifications to footnotes to reflect *resolves* 6 and 8 from Resolution 130 (WRC-97) and *resolves* 1.7 from Resolution 538 (WRC-97)

Depending on the revisions to Resolution **130 (WRC-97)** that are made by WRC-2000, it may be necessary to reflect *resolves* 6 and 8 from that Resolution in modifications to pertinent footnotes. Similarly, depending on the revisions to Resolution **538 (WRC-97)** that are made by WRC-2000, it may be necessary to reflect the *resolves* (1.7) from that Resolution in modifications to pertinent footnotes.

Resolves 8 from Resolution **130** and *resolves* 1.7 from Resolution **538** concerning coordination under Resolution **46**/No. **S9.12** are needed to allow non-GSO FSS systems to coordinate with other non-GSO FSS systems. *Resolves* 6 from Resolution **130** concerning non-GSO FSS systems not claiming protection from GSO networks in the FSS may be needed to implement the intent of WRC-97 and so that the BR or administrations operating GSO FSS systems will not be required under the Radio Regulations to consider interference complaints from administrations operating non-GSO systems.

The following are examples of possible modifications to Nos. **S5.441**, **484A**, **487A**, and **516** to reflect these *resolves*:

MOD S5.441 The use of the bands 4 500-4 800 MHz (space-to-Earth), 6 725-7 025 MHz (Earth-to-space) by the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by geostationary-satellite systems in the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by a non-geostationary-satellite systems in the fixed-satellite service ~~shall be in accordance with the provisions of Resolution 130 (WRC-97)~~is subject to the application of the provisions of No. **S9.12** for coordination with other non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service operating in accordance with the Radio Regulations.

MOD S5.484A The use of the bands 10.95-11.2 GHz (space-to-Earth), 11.45-11.7 GHz (space-to-Earth), 11.7-12.2 GHz (space-to-Earth) in Region 2, 12.2-12.75 GHz (space-to-Earth) in Region 3, 12.5-12.75 GHz (space-to-Earth) in Region 1, 13.75-14.5 GHz (Earth-to-space), 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space), 29.5-30 GHz (Earth-to-space) by a non-geostationary~~ and geostationary~~-satellite systems in the fixed-satellite service is subject to application of the provisions of ~~Resolution 130 (WRC-97). The use of the band 17.8-18.1 GHz (space-to-Earth) by non-geostationary fixed-satellite service systems is also subject to the provisions of Resolution 538 (WRC-97)~~ No. **S9.12** for coordination with other non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service operating in accordance with the Radio Regulations.

MOD S5.487A *Additional allocation:* in Region 1, the band 11.7-12.5 GHz, in Region 2, the band 12.2-12.7 GHz and, in Region 3, the band 11.7-12.2 GHz, are also allocated to the fixed-satellite service (space-to-Earth) on a primary basis, limited to non-geostationary systems and subject to the application of the provisions of ~~Resolution 538 (WRC-97)~~No. **S9.12** for coordination between non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from GSO networks in the broadcasting-satellite service operating in accordance with the Radio Regulations.

MOD S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8-18.1 GHz (Earth-to-space) in Region 2 by non-geostationary-satellite systems in the fixed-satellite service is subject to the application of the provisions of ~~Resolution 538 (WRC-97)~~No. **S9.12** for coordination between non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service operating in accordance with the Radio Regulations.

Reasons: As a result of changes to Resolutions 130 and 538, these modifications to footnotes contained in Article S5 will be needed, including the incorporation of the appropriate *resolves* from these Resolutions.

Option 1B **Example modifications to footnotes to reflect possible modifications to Resolution 130 (WRC-97) and Resolution 538 (WRC-97) that include suppression of *resolves* 6 and transfer of *resolves* 8 from Resolution 130 (WRC-97) and *resolves* 1.7 from Resolution 538 (WRC-97)**

MOD S5.441 The use of the bands 4 500-4 800 MHz (space-to-Earth), 6 725-7 025 MHz (Earth-to-space) by the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by geostationary-satellite systems in the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by non-geostationary-satellite systems in the fixed-satellite service ~~shall be in accordance with the provisions of Resolution 130 (WRC-97)~~is subject to the application of the provisions of No. **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service. The provisions of Resolution **130 (WRC-2000)** apply.

MOD S5.484A The use of the bands 10.95-11.2 GHz (space-to-Earth), 11.45-11.7 GHz (space-to-Earth), 11.7-12.2 GHz (space-to-Earth) in Region 2, 12.2-12.75 GHz (space-to-Earth) in Region 3, 12.5-12.75 GHz (space-to-Earth) in Region 1, 13.75-14.5 GHz (Earth-to-space), 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space), 29.5-30 GHz (Earth-to-space) by non-geostationary~~- and geostationary-~~ satellite systems in the fixed-satellite service is subject to application of the provisions ~~of Resolution 130 (WRC-97). The use of the band 17.8-18.1 GHz (space-to-Earth) by non-geostationary fixed-satellite service systems is also subject to the provisions of Resolution 538 (WRC-97)~~No. **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service. The provisions of Resolutions **130 (WRC-2000)** and **538 (WRC-2000)** apply.

MOD S5.487A *Additional allocation:* in Region 1, the band 11.7-12.5 GHz, in Region 2, the band 12.2-12.7 GHz and, in Region 3, the band 11.7-12.2 GHz, are also allocated to the fixed-satellite service (space-to-Earth) on a primary basis, limited to non-geostationary systems and subject to the application of the provisions of ~~of Resolution 538 (WRC-97)~~No. **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service. The provisions of Resolution **538 (WRC-2000)** apply.

MOD S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8-18.1 GHz (Earth-to-space) in Region 2 by non-geostationary-satellite systems in the fixed-satellite service is subject to the application of the provisions of ~~Resolution 538 (WRC-97).~~No. **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service. The provisions of Resolution **538 (WRC-2000)** apply.

2 Example modifications to footnotes S5.488 and S5.491 to reflect relevant RRB Rule of Procedure

2.1 Limitations concerning subregional systems contained in S5.488 and S5.491

It was noted that footnotes **S5.488** and **S5.491** currently restrict the use by FSS (space-to-Earth) of certain bands in the 12 GHz range to national and subregional systems. In 1998, the Radio Regulations Board adopted a Rule of Procedure on subregional systems, which states that "In the case where a service area covers a territory under the jurisdiction of other administrations, it shall be limited to the territories of the administrations concerned and it shall be notified by one of the participating administrations on behalf of other administrations."

These limitations lead to significant burden to the administrations and the Bureau, and unnecessary constraints on the development of GSO and non-GSO FSS systems, without clear advantage since those administrations associated with the sub-regional system keep the same rights as those which do not associate.

2.2 Application of these footnotes to non-GSO FSS systems

Concerning the application of these two footnotes to non-GSO FSS systems, a Rule of Procedure was adopted by the RRB in April 1998. The Board considered that these provisions should be waived in the case of non-GSO FSS systems in order to align them with the decisions of WRC-97 allowing the development of such systems in these bands.

Concerning the need specified by **S5.488** for previous agreement from administrations which services may be affected, the limitations introduced by WRC-97 in Articles **S21** and **S22** are intended to preclude that such services be affected. Therefore, this restriction does not appear to be applicable to non-GSO FSS systems.

2.3 Possible options

The possible options available with respect to footnotes **S5.488** and **S5.491** are therefore the following:

Option 2A – NOC

Under this option, footnotes **S5.488** and **S5.491** would be maintained unchanged. This would maintain significant burden to the administrations and the Bureau, and unnecessary constraints on the development of global, regional and subregional GSO and non-GSO FSS systems in Regions 2 and 3, without clear advantage. Some administrations considered that there would be a national regulatory risk in changing these provisions.

Option 2B – Exemption of non-GSO FSS systems from the scope of S5.488 and S5.491

Under this option, **S5.488** and **S5.491** may be amended as provided in the example below so as to align the regulatory situation with the Rule of Procedure adopted by the RRB in April 1998 with respect to non-GSO FSS systems. This would allow non-GSO FSS systems, which are by essence global systems, to avoid the constraints resulting from these two footnotes and would align these provisions with the decisions of WRC-97 allowing the development of such systems in these bands.

S5.488 The use of the bands 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 and 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 is subject to previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9** and **S11**). For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

S5.491 *Additional allocation:* in Region 3, the band 12.2-12.5 GHz is also allocated to the fixed-satellite (space-to-Earth) service on a primary basis~~,~~. The use of this allocation by geostationary-satellite networks is limited to national and sub-regional systems. The power flux-density limits in Article **S21**, Table **S21-4** shall apply to this frequency band. The introduction of the service in relation to the broadcasting-satellite service in Region 1 shall follow the procedures specified in Article 7 of Appendix **S30**, with the applicable frequency band extended to cover 12.2-12.5 GHz.

Option 2C – Exemption of both GSO and non-GSO FSS systems from the scope of S5.488 and S5.491

Under this option, **S5.488** and **S5.491** may be amended as provided in the example below, so as to eliminate all restrictions to national and subregional systems for the FSS in the corresponding bands. Concerning the need specified by **S5.488** for previous agreement from administrations which services may be affected, it is to be noted that it might also be waived for GSO FSS systems if pfd limits were to be introduced in Article **S21 (see also Section xxx, PP-98)** to ensure the protection of terrestrial services. This would have the advantage of avoiding any unnecessary constraints on the development of both GSO and non-GSO FSS systems in the corresponding bands in both Regions 2 and 3.

S5.488 The use of the bands ~~11.7-12.2 GHz the fixed-satellite service in Region 2 and~~ 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 is subject to previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9** and **S11**). For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

S5.491 *Additional allocation:* in Region 3, the band 12.2-12.5 GHz is also allocated to the fixed-satellite (space-to-Earth) service on a primary basis~~,~~ ~~limited to national and sub-regional systems~~. The power flux-density limits in Article **S21**, Table **S21-4** shall apply to this frequency band. The introduction of the service in relation to the broadcasting-satellite service in Region 1 shall follow the procedures specified in Article 7 of Appendix **S30**, with the applicable frequency band extended to cover 12.2-12.5 GHz.

3 Example modification to footnote RR No. S5.516 (in addition to modification in No. 1B above) and to footnote RR No. S5.520 if WRC-2000 decides to include limits in the frequency bands 17.3-17.8 GHz (Earth-to-space) in Region 2 and 18.1-18.4 GHz (Earth-to-space) in Regions 1, 2, and 3*

WRC-2000 may determine to impose limits in the bands 17.3-17.8 GHz (Earth-to-space) in Region 2 and 18.1-18.4 GHz (Earth-to-space) in Regions 1, 2 and 3, on the condition that the use of earth stations within non-GSO FSS systems in these bands is limited to gateway stations, in order to limit the number of such stations. This condition could be reflected from a regulatory point of view by imposing a limitation on the minimum antenna diameter (e.g. 4.5 metres). Should WRC-2000 decide to include limits in these frequency bands under this condition, there would be a need to reflect this decision in Article **S5** as follows:

MOD S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1, 2 and 3 ~~and 17.8-18.1 GHz (Earth-to-space) in Region 2~~ by non-geostationary-satellite systems in the fixed-satellite service is subject to the application of the provisions of ~~Resolution **538 (WRC-97)**~~No. **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service. In Region 2, such use is limited to earth station antennas greater than 4.5 metres. The provisions of Resolution **538 (WRC-2000)** apply.

MOD S5.520 The use of the band 18.1-18.4 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. The use of this band by non-geostationary systems in the fixed-satellite service (Earth-to-space) is limited to earth station antennas greater than 4.5 metres and is subject to the application of the provisions of **S9.12** for the coordination with other non-geostationary-satellite systems in the fixed-satellite service (Earth-to-space and space-to-Earth).

4 Example modification to footnote RR No. S5.516 (in addition to modification in No. 1A above) if WRC-2000 decides to limit the 17.3-17.8 GHz (Earth-to-space) band in Region 2 to geostationary FSS operations*

If WRC-2000 determines that in Region 2 the band 17.3-17.8 GHz should continue to be limited to geostationary FSS operations, then the following is an example of a possible additional modification to No. **S5.516**. This modification encompasses the modification to No. **S5.516** in No. 1A above.

* Refer to sections 3.2.2 and 3.2.3 for discussion concerning these bands.

MOD S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8-18.1 GHz (Earth-to-space) in Region 2 by non-geostationary-satellite systems in the fixed-satellite service is subject to the application of the provisions of ~~Resolution 538 (WRC-97)~~No. S9.12 for coordination between non-geostationary-satellite systems in the fixed-satellite service. Non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service operating in accordance with the Radio Regulations. The use of the band 17.3-17.8 GHz in Region 2 by systems in the fixed-satellite service (Earth-to-space) is limited to geostationary-satellites.

5 Example modification to footnote RR No. S5.520 if WRC-2000 determines that the 18.1-18.4 GHz (Earth-to-space) band in Regions 1, 2, and 3 should be limited to geostationary FSS operations

If WRC-2000 determines that the band 18.1-18.4 GHz should be limited to geostationary FSS operations in the Earth-to-space direction in Regions 1, 2, and 3, then the following is an example of a possible modification to RR No. **S5.520**.

MOD S5.520 The use of the band 18.1-18.4 GHz by the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service using the geostationary-satellite orbit.

ANNEX ~~1~~7 TO CHAPTER 3

Examples of possible modifications to Section VI of Article S22

Three options were identified for how the off-axis e.i.r.p. issue should be considered. The following text includes examples of possible modifications to Section VI of Article **S22** for each of these options. In case of option 2 the example is intended for GSO FSS earth stations, recognizing that the current provisions of Section VI of Article **S22** are suspended until the review of these limits by WRC-2000 (RR **S22.VI.1**)[11].

[11] **S22.VI.1** The provisions of this section are suspended pending the review of the values in Nos. **S22.26**, **S22.27** and **S22.28** by WRC-~~99~~2000.

Option 1

Suppress the current Section VI of Article **S22** of the Radio Regulations. Thus no FSS earth station off-axis e.i.r.p. limitations would be included in the Radio Regulations.

SUPPRESS current Section VI of Article **S22**.

Option 2

Example of off-axis e.i.r.p. limits in Section VI of Article **S22** for GSO FSS earth stations in some Earth-to-space frequency bands 12.75-13.25 GHz, 13.75-14 GHz, 14-14.5 GHz and 29.5-30 GHz.

It is noted that the current Section VI of Article S22 is not restricted to GSO FSS earth stations. Further studies are required to the applicability of values in Section VI to non-GSO FSS earth stations (see § 3.1.2.2.6).

REPLACE current Section VI of Article **S22** by the following text.

Section VI – GSO ~~E~~earth station off-axis power limitations in the fixed-satellite service[11]

MOD S22.26 § 9 The level of equivalent isotropically radiated power (e.i.r.p.) emitted by an earth station within a geostationary-satellite network shall not exceed the following values for any off-axis angle φ which is ~~2.5~~3° or more off the main-lobe axis of an earth station antenna:

Off-axis angle	Maximum e.i.r.p. density
~~2.5~~3° ≤ φ ≤ 7°	(~~39~~42-25 log φ) dB(W/40 kHz)
7° < φ ≤ 9.2°	~~18~~21 dB(W/40 kHz)
9.2° < φ ≤ 48°	(4~~2~~5-25 log φ) dB(W/40 kHz)
48° < φ ≤ 180°	~~0~~3 dB(W/40 kHz)

MOD S22.27 For FM-TV emissions with energy dispersal, the limits in No. **S22.26** above may be exceeded by up to 3 dB provided that the off-axis total e.i.r.p. of the transmitted FM-TV carrier does not exceed the following values:

Off-axis angle	Maximum e.i.r.p.
~~2.5~~3° ≤ φ ≤ 7°	(~~53~~56-25 log φ) dBW
7° < φ ≤ 9.2°	~~32~~35 dBW
9.2° < φ ≤ 48°	(~~56~~59-25 log φ) dBW
48° < φ ≤ 180°	~~14~~17 dBW

MOD S22.28 FM-TV carriers which operate without energy dispersal should be modulated at all times with programme material or appropriate test patterns. In this case, the off-axis total e.i.r.p. of the emitted FM-TV carrier shall not exceed the following values:

Off-axis angle	Maximum e.i.r.p.
~~2.5~~3° ≤ φ ≤ 7°	(~~53~~56-25 log φ) dBW
7° < φ ≤ 9.2°	~~32~~35 dBW

9.2° < φ ≤ 48°	(~~56~~59-25 log φ) dBW
48° < φ ≤ 180°	~~14~~17 dBW

NOC S22.29 The e.i.r.p. limits given in Nos. **S22.26**, **S22.27** and **S22.28** are applicable in the following frequency bands allocated to the fixed-satellite service (Earth-to-space):

12.75-13.25 GHz

13.75-14 GHz

14-14.5 GHz.

ADD S22.30 The e.i.r.p. limits given in Nos. **S22.26, S22.27** and **S22.28** do not apply to earth station antennas ready to be in service[12] prior to 2 June 2000 nor to earth stations associated with a satellite network in the fixed-satellite service for which complete coordination or notification information has been received before 2 June 2000.

ADD S22.30.1 [12] "Ready to be in service" relates to the case where antennas have been installed but the start of service has been delayed due to *force majeure*.

ADD S22.31 Telecommand and ranging carriers transmitted to geostationary satellites in the fixed-satellite service in normal mode of operation (i.e. earth station transmitting telecommand and ranging carriers to a directive receiving antenna on the space station) may exceed the levels given in **S22.26** by no more than 16 dB in the frequency bands 12.75-13.25 and 13.75-14.5 GHz. In all other modes of operation, and in case of *force majeure*, telecommand and ranging carriers transmitted to geostationary satellites in the fixed-satellite service are exempted from the levels given in **S22.26**.

ADD S22.32 § 10 The level of equivalent isotropically radiated power (e.i.r.p.) density emitted by an earth station within a geostationary-satellite network in the 29.5-30.0 GHz frequency band shall not exceed the following values for any off-axis angle φ which is 3° or more off the main-lobe axis of an earth station antenna:

Off-axis angle	Maximum e.i.r.p. density*
3° ≤ φ ≤ 7°	(28-25 log φ) dB(W/40 kHz)
7° < φ ≤ 9.2°	7 dB(W/40 kHz)
9.2 < φ ≤ 48°	(31-25 log φ) dB(W/40 kHz)
48° < φ ≤ 180°	1 dB(W/40 kHz)

ADD S22.33 The e.i.r.p. limits given in **S22.32** do not apply to earth station antennas ready to be in service prior to [XXXX] nor to earth stations associated with satellite networks in the fixed-satellite service which have been brought into use before 2 June 2000.

* The above values are 6 dB higher than the corresponding values in Recommendation ITU-R S.524-5 (Doc. 4/66).

ADD **S22.34** Telecommand and ranging*** carriers transmitted to geostationary satellites in the fixed-satellite service in normal mode of operation (i.e. earth station transmitting telecommand and ranging carriers to a directive receiving antenna on the space station) may exceed the levels given in **S22.32** by no more than 10 dB** in the frequency band 29.5-30.0 GHz.

In all other modes of operation, and in case of *force majeure,* telecommand and ranging carriers transmitted to geostationary satellites in the fixed-satellite service are exempted from the levels given in **S22.32.**

ADD **S22.35** For GSO systems in which the earth stations are expected to transmit simultaneously in the same 40 kHz band, e.g. for the GSO systems employing CDMA, the maximum e.i.r.p., values in **S22.32** should be decreased by 10*log(N) dB, where N is the number of earth stations which are in the receive satellite beam of the satellite to which these earth stations are communicating and which are expected to transmit simultaneously on the same frequency.

ADD **S22.36** Earth stations operating in the 29.5-30 GHz frequency band should be designed in such a manner that 90% of the their peak off-axis e.i.r.p. density levels do not exceed the values given in **S22.32**. Further study is needed to determine the off-axis angular range over which these exceedances would be permitted, taking into account the interference level into adjacent satellites. The statistical processing of the off-axis e.i.r.p. density peaks should be dealt with using the method given in Recommendation ITU-R S.732.

ADD **S22.37** The values given in **S22.32** are maximal values under clear-sky conditions. In case of systems employing uplink power control, these levels include any additional margins above the minimum clear-sky level necessary for the implementation of uplink power control. During rain faded conditions, the levels in **S22.32** may be exceeded by earth stations when implementing uplink power control.

ADD **S22.38** FSS earth stations operating in the 29.5-30 GHz band, which have lower elevation angles to the GSO will require higher e.i.r.p. levels relative to the same terminals at higher elevation angles to achieve the same power flux-densities at the GSO due to the combined effect of increased distance and atmospheric absorption. Earth stations with low elevation angles may exceed the levels given in **S22.32** by the following amount:

Elevation angle to GSO (ε)	Increase in e.i.r.p. density (dB).
$\varepsilon \leq 5°$	2.5
$5 < \varepsilon \leq 30°$	$0.1(25 - \varepsilon) + 0.5$

ADD **S22.39** The values in **S22.32** applicable to the off-axis angle range from 48° to 180° is intended to account for spillover effects.

*** Measurement of the distance to the satellite.

** Further studies are required to confirm the value of 10 dB.

Option 3

Example of incorporation by reference of an ITU-R Recommendation, when available, to specify off-axis e.i.r.p. limits in Section VI of Article **S22** for FSS earth stations in some Earth-to-space frequency bands that are specified in Resolution **130**.

SUPPRESS Section VI of Article **S22.**

MOD S22.26 § 9 The level of equivalent isotropically radiated power (e.i.r.p.) emitted by an earth station shall not exceed the ~~following~~ values ~~for any off-axis angle φ which is 2.5° or more off the main lobe axis of an earth station antenna:~~included in an appropriate Recommendation.

ANNEX 8 TO CHAPTER 3

1 Example procedure for assuring compliance with aggregate EPFD limits

When an administration operating a GSO network in accordance with the Radio Regulations identifies EPFD levels from non-GSO systems in excess of the "aggregate" limits given in Annex 1 of Resolution **WWW**:

a) The affected administration shall immediately send a letter, by fax or other mutually agreed electronic means, to the administrations concerned and request immediate corrective action. It shall provide the necessary evidence identifying the excess interference and the source of such interference. A copy of the request shall be sent to the BR.

b) Upon receipt of the request, the interfering administrations shall acknowledge receipt within [X] days and immediately reduce emissions, equitably, to the required levels pending final determination of solutions to the problem. A copy of the acknowledgement and confirmation of the action taken shall be sent to the BR.

c) The non-GSO parties concerned work together thereafter in order to find a permanent solution to the problem, within an additional [30] days.

d) If after [30] days a solution cannot be found, then any of the parties may request the assistance of the BR.

e) The BR will study the matter and report its conclusion to the parties involved, recommending its solution to the problem within an additional [30] days. The affected administration may elect to accept the higher level of interference received.

f) If an interfering administration fails to respond within the [X]-day period in Step 3, the affected administration shall send a reminder fax requesting response within an additional [X] days.

g) If any administration fails to respond within that period, the affected administration may request the assistance of the Bureau, who will promptly send a fax to the concerned administrations.

h) See 3.1.6.1 for the case the administration fails to respond to the BR's request for cooperation.

2 Example procedure for assuring compliance with operational limits

When an administration operating a GSO network in accordance with the Radio Regulations identifies EPFD levels from non-GSO systems in excess of the "operational limit" given in Table **S22-4**, as determined by the use of ITU-R agreed measurement techniques or until such ITU-R agreed measurement techniques are available by use of the actual earth station monitoring capability:

a) That administration first attempts to identify the source of the excess EPFD.

b) If the source of the excess EPFD is readily identifiable, the administration may proceed to Step 8 below.

c) In case, after Step 1, an administration is unable to determine the source of interference, it shall send a request for cooperation to all administrations responsible for non-GSO systems using over-lapping frequency bands, providing all relevant details. A copy of the request shall be sent to the BR.

d) The requested administrations shall acknowledge receipt immediately and dispatch to the requesting administration within [y] days, with a copy to the BR, the information which may be used to identify the source of the problem.

e) If an administration fails to respond within [y] days, the affected administration shall follow up with a reminder by fax with a request for response within an additional [y] days.

f) If the administration still fails to respond, the affected administration may request the assistance of the BR, in which case the BR shall immediately send a fax to the administration responsible for the non-GSO system, requesting action within an additional [z] days.

g) See 3.1.6.2 for the case where the administration fails to respond to the BR's request for information.

h) Once the sources of the excess EPFD are identified, the affected administration sends a letter, by fax or other mutually agreed electronic means, to the administrations concerned and requests immediate corrective action. It shall provide the necessary evidence identifying the amount of excess interference and the source of such interference. A copy of the request shall be sent to the BR.

i) Upon receipt of the request, the interfering administration shall immediately reduce emissions to the required levels pending final determination of solutions to the problem and, within [y] days, so advise the administration whose network is affected. A copy of the acknowledgement and confirmation of the action taken shall be sent to the BR.

j) See comments in 3.1.6.2 on the possibility of arriving at an alternative solution.

k) The BR will study the matter within an additional [30] days, and report its conclusion to the parties involved, recommending its solution to the problem.

ANNEX 9 TO CHAPTER 3

Additional data items required in Appendix S4 for the EPFD calculations

1 Section A.4b

ADD In addition, if the stations operate in a frequency band subject to the provisions of Resolution **130 (WRC-97)** or Resolution **538 (WRC-97)**:

6) new data elements required to characterize properly the orbital operation of the non-GSO satellite systems:

a) for each range of latitudes provide:

– the maximum number of non-GSO satellites operating their downlinks co-frequency to any location; and

– the associated latitude range;

b) the minimum height of the space station above the surface of the Earth at which any satellite will be used to provide a service;

c) where the space station uses station keeping to maintain a repeating ground track, the time in seconds that it takes for the constellation to return to its starting position, i.e. such that all satellites are in the same location with respect to the Earth and each other;

d) an indicator identifying if the space station should be modelled with a specific precession rate of the ascending node of the orbit instead of the J_2 term;

e) for a space station that is to be modelled with a specific precession rate of the ascending node of the orbit instead of the J_2 term, the precession rate in degrees/day, measured counter-clockwise in the equatorial plane;

f) the longitude of the ascending node for the *j*-th orbital plane, measured counter-clockwise in the equatorial plane from Greenwich meridian to the point where the satellite makes its south-to-north crossing of the equatorial plane ($0° \leq \Omega_j < 360°$) (NOTE 1);

g) the time at which the satellite is at the location defined by Ω_j (NOTE 1);

h) the longitudinal tolerance of the longitude of the ascending node.

NOTE 1 - Currently non-GSO space stations are referenced by the "right ascension of ascending node" (A.4b5 Ωj) to the first point of Aries. However, for the evaluation of EPFD a reference to a point on the Earth is used and hence the "longitude of the ascending node" is required.

2 Section A.4b

ADD 7) new data elements required to characterize properly the performance of the non-GSO satellite systems:

a) the maximum number of non-GSO satellites receiving simultaneously [co-frequency] from the associated earth stations within a given cell;

b) the average number of associated earth stations operating co-frequency per square kilometre within a cell;

c) the average distance between co-frequency cells;

d) for the exclusion zone about the geostationary orbit provide:

– the type of zone;

– the width of the zone in degrees.

3 Section A.14

ADD **A.14 Spectrum masks**

For stations operating in a frequency band subject to the provisions of Resolution **130 (WRC-97)** or Resolution **538 (WRC-97)**:

a) for each e.i.r.p. mask used by the non-GSO space station provide:

– the type of mask;

– the mask identification code;

– the mask pattern defined in terms of the power in the reference bandwidth for a series of off-axis angles with respect to a specified reference point;

– the lowest frequency for which the mask is valid;

– the highest frequency for which the mask is valid;

b) additionally for each associated earth station e.i.r.p. mask provide:

– the minimum elevation angle at which any associated earth station can transmit to a non-GSO satellite;

– the minimum separation angle between the GSO arc and the associated earth station beam-axis at which the associated earth station can transmit towards a non-GSO satellite;

c) for each pfd mask used by the non-GSO space station provide:

– the mask identification code;

– the mask pattern of the power flux-density defined in three dimensions;

– the lowest frequency for which the mask is valid;

– the highest frequency for which the mask is valid.

4 Section C.9

ADD *d)* For stations operating in a frequency band subject to the provisions of Resolution **130 (WRC-97)** or Resolution **538 (WRC-97)**, provide:

– the type of mask;

– the mask identification code.

CHAPTER 4

Space science services and radio astronomy

(WRC-2000 agenda items 1.16, 1.17)

CONTENTS

4.1 Agenda item 1.16

"to consider allocation of frequency bands above 71 GHz to the Earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution **723 (WRC-97)**"

***Resolution** 723 (WRC-97) "Consideration by a future competent world radiocommunication conference of issues dealing with allocations to science services"*

4.1.1 Summary of technical and operational studies including consideration of Resolution 723 (WRC-97)

4.1.1.1 Services allocated in the 71-275 GHz frequency range

The frequency range under consideration includes exclusive allocations to the passive services, as well as some shared, co-primary allocations with the fixed (FS), mobile (MS), inter-satellite (ISS) and fixed-satellite (FSS) services. The passive services are also allocated by footnotes No. **S5.149** and No. **S5.340** to a number of bands and/or sub-bands that are shared with other services. The amateur (AS), amateur-satellite (ASS), radiolocation (RLS), radionavigation (RNS), radionavigation-satellite (RNSS), broadcasting (BS), broadcasting-satellite (BSS), mobile-satellite (MSS), ISS and FSS have primary allocations, and the space research (space-to-Earth), amateur, amateur-satellite and radiolocation have secondary allocations in the frequency range 71-275 GHz.

4.1.1.2 Scientific requirements for radio astronomy above 71 GHz

4.1.1.2.1 Importance of the millimetre and decimillimetre bands for radio astronomy

Radio astronomy at millimetre and decimillimetre wavelengths developed greatly during the last two decades, and is possibly the fastest growing area within radio astronomy. Growth is driven by the scientific opportunities available only in this frequency range, (e.g. in astrochemistry, physics of stellar and circumstellar envelopes, formation of stars, planets and protoplanets, chemical composition of the interstellar medium, physical conditions in the early Universe and Galaxy formation, etc.) which has been made possible by technological developments, such as, the availability of low noise receivers and the development of millimetre wave instrumentation in general. Ground-based radio telescopes in the mm-range are currently operated by administrations in all three ITU Regions, up to frequencies of 900 GHz.

Millimetre-wave observatories represent a major investment and are, therefore, required to maximize their scientific return. Consequently, great care is being taken to locate them at the best possible sites. To cover the entire sky, there is a need to have access to good observing sites in both the northern and southern hemispheres. Extremely dry locations at high elevations are preferred. Several large telescopes (interferometers and single dish telescopes), that will cover the millimetre and decimillimetre wavelength ranges are either under construction or in advanced stages of planning. The US-European Atacama Large Millimeter Array (ALMA), and the Japanese Large Millimeter and Submillimeter Array (LMSA) are to be located in Chile, and will likely be combined into one international megascience project. Other large telescopes under construction are the US Smithsonian Astrophysical Observatory's Submillimeter Array (SMA) and the Large Millimeter Telescope (LMT), a US-Mexico collaborative project, being built in Mexico. In addition to these large international facilities there are some others scattered around the world, that have a more restricted range of applications.

As an example of the new telescopes using the most up-to-date technology, the ALMA-LMSA is planned to consist of 40-60 parabolic antennas of 12-metre diameter. From just above the oxygen absorption band near 60 GHz to near 850 GHz in the decimillimetre range, there will be a series of receivers at each antenna which will cover most of the spectrum. The remoteness of the site will allow access to most of the millimetre wavelength spectrum, except that which contains emissions from satellites or aircraft.

Observations at millimetre-decimillimetre wavelengths from space also contribute significantly to several areas of radio astronomy. Sharing criteria applicable to ground-based radio astronomy are usually not applicable to radio astronomy from space.

4.1.1.2.2 Access to spectral lines of importance to radio astronomy (71-275 GHz)

Over 2 100 spectral lines of 80 chemical compounds have been identified to date, many detected lines are yet to be identified, and more species and lines are predicted. Many of the lines are astrophysically very important (see e.g. Recommendation ITU-R RA.314-8), and interest in others may be triggered by new discoveries. To facilitate sharing of the spectrum with other users, the International Astronomical Union (IAU) periodically revises the list of lines of most astrophysical interest. Radio astronomers are interested in preserving access to as many of these spectral lines as possible, because they may yield unique information about physical processes in certain celestial objects.

Astronomical discoveries of new molecular species have stimulated other scientific fields such as molecular spectroscopy and quantum chemistry, with potential practical applications. One example of a discovery directly stimulated by millimeter-wave radio astronomy is the discovery of fullerenes, first detected in the laboratory experiments designed to understand the chemistry in atmospheres of giant stars, observed to produce abundant long carbon-chain molecules, which brought about the development of an entire new branch of chemistry.

There are also many astrophysically important spectral lines at frequencies above 275 GHz (see e.g. Recommendation ITU-R RA.314-8). Many millimetre/decimillimetre observatories now operate up to 900 GHz and space-borne telescopes will soon operate above 1 000 GHz. Table 4-1 lists the frequency bands in the 71-275 GHz range, containing most spectral lines of interest to radio astronomy that are accessible from the ground.

TABLE 4-1

Frequency range (GHz)	Number of detected molecular lines	Lines listed in Recommendation ITU-R RA.314-8
71.0-86.0	326	1
86.0-92.0	224	7
92.0-94.0	21	1
94.1-105.0	322	1
105.0-116.0	194	4
136.0-170.0	208	3
200.0-209.0	9	0
215.0-217.0	49	0
217.0-231.0	321	3
231.0-265.0	450	1
265.0-275.0	15	3

4.1.1.2.3 Radio astronomy service requirements above 275 GHz

The current Table of Frequency Allocations does not extend above 275 GHz. However, there are already a number of radio astronomy observatories equipped to observe in this area of the spectrum and scientific requirements of the large international facilities now under development certainly include plans for observations up to about 900 GHz. No. **S5.565** currently notes that the bands 278-280 GHz and 343-348 GHz are identified as bands that should be protected for use by the RAS. Additionally, the bands 275-323 GHz, 327-371 GHz, 388-424 GHz, 426-442 GHz, 453-510 GHz, 623-711 GHz and 795-909 GHz have been identified as bands that are or that will be used by radio observatories in the future.

4.1.1.2.4 Radio astronomy receiver characteristics in the millimetre wavelengths

Wide frequency bandwidth coverage is required in radio astronomy, to enable sensitive observations of faint objects, such as extra-solar planetary systems, or very distant galaxies. The sensitivity of an observation increases in proportion to the square root of the bandwidth, and recent technology enables using bandwidth of up to 8 GHz in heterodyne receivers. In addition wide frequency coverage is needed to observe the highly red-shifted[1] objects that are characteristic of the early Universe. For example, highly Doppler-shifted ("red-shifted") CO lines, from about ten billion years ago, have been observed recently at about 1/5 of the rest frequency of the line. Such observations provide crucial information on the formation of galaxies, and the history of the early Universe, not obtainable by other methods. Very sensitive observations are now also possible using very wide bandwidth bolometer detectors. These require bandwidths of several tens of GHz and many involve arrays of detectors of up to a hundred individual elements. Such devices are in use at several radio astronomy observatories and need the protection provided by continuum allocations. These instruments are also leading the development of new and innovative radio technologies.

The instrumentation used at millimetre-wave observatories lies at the very forefront of radio technology. Much of this instrumentation is particularly susceptible to interference. For example, many modern systems employ SIS (Superconductor-Insulator-Superconductor) mixers, which are subject to temporary saturation or permanent burnout at very low power densities. These devices are achieving noise temperatures close to the quantum limit. Development of systems with improved rejection of out-of-band signals is an important priority for future research.

4.1.1.3 Scientific requirements for spaceborne passive sensing above 71 GHz

Within the frequency range under consideration, sensors on board satellites operating in the EESS (passive) and SRS (passive) can be collectively described as "spaceborne passive sensors".

4.1.1.3.1 Scientific requirements for spaceborne passive sensing in the 71-275 GHz range

Almost all of the current spaceborne passive sensing allocations in the range 71-275 GHz were decided by WARC-79. Many technological and scientific advances and discoveries have occurred since that time and these allocations need to be revised to reflect present and foreseeable future requirements for spaceborne passive sensing for a myriad of Earth observation applications including agriculture, climatology, meteorology and study of global change of the Earth and its

---

[1] The rest frequency of a spectral line is the frequency that is observed in a rest frame, e.g. in the laboratory. Celestial objects, outside our Galaxy, recede with a velocity that is proportional to their distance from us, and consequently spectral lines that originate in these objects appear to us Doppler-shifted towards lower frequencies ("red-shifted").

environment. Increased awareness of the stress being placed on the Earth system has led the global user community, including the World Meteorological Organization, Global Climate Observing System, and World Climate Research Programme, to define satellite data requirements for atmospheric parameters including temperature and water vapour profiles, ozone concentration, and other radiatively and chemically active trace gases, which can only be met by satellite passive sensors. The frequency range 71-275 GHz is fundamental to the achievement of these important sensing capabilities.

Information on the spaceborne passive sensing spectrum requirements in the range 71-275 GHz are given in Table 4-2. General comments on the scientific applications of each of these bands is also given. It should be noted that many atmospheric constituent lines (e.g. nitrous oxide, carbon monoxide, chlorine, ozone, etc.) exist throughout this frequency range and only those lines deemed most critical have been included in the table. Furthermore, multiple lines attributed to the same atmospheric constituent are often required in order to map out the atmospheric concentrations at different altitudes.

TABLE 4-2

Bands required for spaceborne passive sensing (GHz)	**Scientific applications**
86-92	Reference window used in conjunction with the oxygen absorption band around 118.75 GHz. Band also used for clouds and precipitation measurements.
100-102	Band contains a nitrous oxide line near 101 GHz for atmospheric limb sounding.
109.8-111.8	Band contains ozone line at 110.8 GHz for microwave limb sounding.
114.25-122.25	Band is a unique natural resource for sounding the temperature of the lower troposphere from geostationary orbiting passive sensors using the oxygen absorption line at 118.75 GHz. Also, contains carbon monoxide line at 115.27 GHz for microwave limb sounding.
148.5-151.5 and 164-167	These bands are necessary to collect meteorological information at the Earth's surface as well as near the surface of the Earth and is used in conjunction with the water vapour line near the 183.31 GHz for atmospheric sounding. Additionally, these bands contain a nitrous oxide line at 150.74 GHz and a ClO line at 164.38 GHz for microwave limb sounding.
174.8-191.8	This band is a unique natural resource to provide a complete tropospheric water vapour vertical profile from LEO passive sensors and from geostationary orbiting passive sensors using the water vapour absorption line whose peak is at 183.31 GHz.
200-209	This band is the important band for microwave limb sounding of various atmospheric constituents in the stratosphere and troposphere.
226-231.5	This band is required for microwave limb sounding of various atmospheric constituents and also to provide 4 GHz reference window for water vapour sounding near 325 GHz.
235-238	This band contains two critical ozone lines for microwave limb sounding of the atmosphere at 235.71 GHz and 237.15 GHz.
250-252	This band contains a nitrous oxide line near 251 GHz for use for microwave limb sounding applications.

4.1.1.3.2 Scientific requirements for spaceborne passive sensing above 275 GHz

The current Table of Frequency Allocations does not extend above 275 GHz. However, there are already spaceborne passive sensors utilizing frequency bands in this area of the spectrum and many more are planned for other bands in the future. No. **S5.565** currently notes that the bands 275-277 GHz, 300-302 GHz, 324-326 GHz, 345-347 GHz, 363-365 GHz, and 379-381 GHz are identified as bands that should be protected for use by spaceborne passive sensors. Additionally, the bands 294-306 GHz, 316-334 GHz, 342-349 GHz, 371-389 GHz, 416-434 GHz, 442-444 GHz, 496-506 GHz, 546-568 GHz, 624-629 GHz, 634-654 GHz, 659-661 GHz, 684-692 GHz, 730-732 GHz, 851-853 GHz and 951-956 GHz have been identified as bands that will also be used for spaceborne passive sensing.

4.1.1.3.3 Passive sensing requirements not clearly identified within agenda item 1.16

Terrestrial passive sensing is performed in a number of frequency bands above 71 GHz (200-209 GHz, 235-238 GHz, 250-252 GHz which have primary allocations for Earth exploration-satellite (passive) and 265-275 GHz which has no allocation for Earth exploration-satellite (passive)). However, this activity may not fall within the definition of any ITU radiocommunication service. Instead, No. **S1.51** possibly relates it to the Earth exploration-satellite service by referring to Earth-based platforms. Therefore, the need for a definition of such a service could be reviewed by WRC-2000 under agenda item 1.16 to facilitate consideration of allocation requirements at a future competent conference.

4.1.1.4 Studies in the frequency range above 71 GHz

A number of studies have been carried out by various administrations, leading to the following existing Recommendations:

ITU-R RA.314-8, RA.611-2, RA.769-1, RA.1031-1, RA.1272, SA.515-3, SA.1028-1 and SA.1029-1.

Recommendation ITU-R SA.1416 addressing the feasibility of sharing between spaceborne passive sensors and inter-satellite links of GSO and non-GSO satellite networks near 118 and 183 GHz has been developed.

4.1.2 Analysis of the results of the studies

Sharing studies have been limited to frequencies below 275 GHz.

4.1.2.1 Sharing between the RAS and other services

4.1.2.1.1 Sharing between the RAS and terrestrial services

Active terrestrial services allocated above 71 GHz include the FS, MS, AS, RLS, RNS and BS. No sharing studies between the RAS and these services have been performed yet within the ITU, because few or no parameters are available to characterize the services with which sharing needs to be assessed in this spectral region. Sharing between terrestrial services and ground-based radio astronomy is considered feasible, however, because of the limited number of existing and planned radio astronomy stations worldwide, and their remote location (Recommendation ITU-R RA.1272), Administrations may establish coordination zones around millimetre-wave astronomical observatories. Coordination radii of the order of 100 km may be necessary. Assuming, for example an absorption coefficient of 0.5 dB/km, spreading and propagation losses over a distance of 100 km amount to about 150 dB. The power flux-density due to a 1 kW omnidirectional transmitter at a distance of 100 km is then typically -120 dB(W/m^2). Detrimental power flux-densities for continuum radio observations in astronomy bands above 71 GHz listed in Recommendation ITU-R RA.769-1, Table 1, range from -125 dB(W/m^2) at 89 GHz to -113 dB(W/m^2) at 270 GHz. For spectral line observations, Table 2 of the same Recommendation gives values ranging from -144 dB(W/m^2) at 88.6 GHz to -131 dB(W/m^2) at 265 GHz. Taking advantage of terrain shielding, already done at some operating millimetre-wave observatories, may reduce the size of the required coordination zone. Recommendation ITU-R RA.1272 notes the need for further studies of the size of the coordination zone.

Because of the relatively small area of the coordination regions required, the RAS should be able to share with terrestrial services with minimum impact, by means of geographical sharing, time-sharing, or both. Geographical and/or time-sharing should be possible between the RAS and the fixed, mobile, amateur and radiolocation services. The possible exception is the broadcasting service, with which sharing may be difficult or may require large coordination radii because of the high power levels employed by this service. Given that new allocations to the RAS are intended to be used at only a few remote locations worldwide, the RAS could accept a footnote, limiting additional allocations to be shared with terrestrial services, to coordination zones around observatories.

4.1.2.1.2 Sharing between the RAS and the MSS and FSS

Sharing between MSS and FSS uplinks and the RAS are no different from sharing with the terrestrial services, and should be manageable by geographical separation. The impact of satellite downlinks on radio astronomy at all frequencies is discussed in Recommendation ITU-R RA.611-2. It is concluded that sharing with satellite downlinks is not possible except through time-sharing or through sharing on a regional basis.

Millimetre wave radio observatories are particularly vulnerable to even very low levels of unwanted emissions. Particular care should therefore be taken in the millimetre range of the spectrum to avoid out-of-band emission problems between the RAS and satellite service downlinks that may be used globally. Therefore, it is of great interest to avoid adjacent allocations between the RAS and satellite services in the space-to-Earth direction as much as possible. To minimize adjacent allocation concerns, and to enable the passive services to have access to the widest possible bandwidth, allocations to satellite downlinks should be moved close to the edges of the atmospheric windows[2]. In doing so, care should be taken to avoid shifting satellite downlinks to spectral regions of atmospheric opacity that would render their operation difficult or impossible, when they develop plans to use the 71-275 GHz range.

4.1.2.1.3 Sharing between the RAS and the BSS

The large areas of the Earth illuminated by the BSS and the high power levels that are likely to be employed make sharing with this service particularly difficult for the radio astronomy service.

4.1.2.1.4 Sharing between the RAS and the RNSS, ASS and SRS (active)

Line-of-sight sharing between the RAS and the RNSS, the ASS and the SRS (active) is not feasible. No satellites are known to operate above 71 GHz at present in these services. When systems become operational at these frequencies, it is expected that the number of satellites will be limited, and their

[2] The atmospheric windows are spectral regions of low atmospheric opacity. In contrast to these windows, strong absorption lines centred on approximately 118 GHz and 183 GHz, render the atmosphere opaque to radio waves near these frequencies.

orbital elements will be known. With exception of the radionavigation-satellite service, time-sharing these bands may be possible, as radio astronomy stations could schedule observations at those times when no satellite is above the horizon.

4.1.2.1.5 Sharing between the RAS and the ISS

Most bands allocated to the ISS are in spectral regions of high atmospheric opacity. No sharing studies between the RAS and the ISS have been conducted to date, due to lack of parameters to characterize the ISS systems. There is a need to carry out such studies as soon as possible. Some bands allocated to the ISS contain spectral lines of interest to the RAS, and shared allocations for the RAS may be sought in these. In the absence of sharing studies no operational restrictions should be placed on the ISS as far as ground-based radio astronomy is concerned. Line-of-sight sharing between the ISS and space-based radio astronomy stations may not be possible.

4.1.2.2 Sharing between EESS (passive) and other services

4.1.2.2.1 Sharing between EESS (passive) and the terrestrial services

Considering the bands currently shared or potentially shared in the future between the above services, ITU-R studies indicates that sharing between EESS (passive) and the fixed service is generally feasible in bands of high atmospheric absorption. Sharing in many bands may require constraints on the fixed service in order to protect the spaceborne passive sensors. In bands where the interference threshold for passive sensors may not be exceeded more than 0.01% of the measurement cells in the sensor's service area as given in Recommendation ITU-R SA.1029-1, sharing may be technically feasible, but not practicable due to the necessary constraints on the fixed service, in order for them to respect the interference threshold and data availability criteria.

In particular, studies on sharing between these two services in the bands 114.25-122.25 GHz and 174.8-191.8 GHz have indicated that sharing between spaceborne passive sensors and the fixed service may only be feasible under very stringent conditions and therefore may not be practicable. One study on sharing between microwave limb sounders and the fixed service in the bands 200-275 GHz concluded that sharing was not feasible while another study indicated that sharing may be feasible given certain assumptions.

The feasibility of sharing between the EESS (passive) and the mobile and amateur services are considered similar to the feasibility of sharing between the EESS (passive) and the fixed service.

4.1.2.2.2 Sharing between EESS (passive) and the ISS

Studies have indicated that sharing in the bands 116-122.25 GHz and 174.8-190 GHz between spaceborne passive sensors of the EESS and the ISS is feasible if the ISS is limited to satellites in the geostationary orbit with suitable pfd limits as given in Recommendation ITU-R SA.1416.

4.1.2.2.3 Sharing between EESS (passive) and the MSS, FSS and BSS

Sharing between spaceborne passive sensors and the MSS, FSS and BSS operating in the Earth-to-space direction is generally not feasible due to the direct mainlobe interference that results whenever an earth station of one of these services is in view of the sensor. Sharing between the spaceborne passive sensors and these services in the space-to-Earth direction has not been studied due to the lack of information available on potential systems in these services. Additionally, the interference mode that would need to be analysed to determine if sharing is feasible involves examining reflections of satellite emissions off the surface of the Earth. There is insufficient information on modelling such reflections at these frequencies. However, experience in other bands indicates that severe data loss to the sensor can occur from this type of interference.

Determination of sharing feasibility between passive microwave limb sounders and these satellite services would require further study.

4.1.2.2.4 Sharing between EESS (passive) and RNSS and ASS

The feasibility of sharing between spaceborne passive sensors and the radionavigation-satellite and amateur-satellite services are considered similar to the feasibility of sharing between the spaceborne passive sensors and the MSS, FSS, and BSS services. The major difference is that there would potentially be a limited number of satellites in these services when systems become operational at these frequencies.

4.1.2.2.5 Sharing between EESS (passive) and radiolocation and radionavigation services

Sharing between spaceborne passive sensors and the radiolocation and radionavigation services is not feasible.

4.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

In proposing to satisfy the agenda item, the following considerations should be kept in mind:

1) Passive allocations should be made in response to observational requirements determined by natural (e.g. astrophysical or atmospheric) processes.

2) Passive allocations in the range 71-275 GHz need to be revised to reflect current scientific requirements. There is a continued requirement for allocations for some exclusive passive bands in the millimetre-wave region, because:

   a) passive sensors of the EESS (passive) are operated on a global basis and coordination with other services is generally not practical;

   b) space-based radio telescopes can observe in bands of high atmospheric opacity that may not be observed from the ground;

   c) space-based radio telescopes are also used in conjunction with ground-based radio telescopes for VLBI, and some allocations are needed which are accessible to both terrestrial and space-based radio telescopes;

   d) passive sensor atmospheric measurements are also taken from Earth-based platforms in many passive bands.

3) The 71-275 GHz part of the Table of Frequency Allocations was adopted at WARC-79, as what was then thought to be a reasonable balance among the various services that are involved. While the technology for the active services has not yet been developed to a level that would permit the use of these services, it is foreseen that the technology is going to be available and that active service systems will be implemented in the future. Based on the rapidly increasing use of the frequency bands below 71 GHz by the active services, it is clear that future systems will be required to operate in the frequency bands above 71 GHz. Consequently, any changes to the frequency allocations in the 71-275 GHz range must continue to accommodate active service requirements. In particular, as much as practicable:

   a) changes regarding the spectrum allocated to other services above 71 GHz should be minimized, in particular in terms of the amount of spectrum, frequency separation between space-to-Earth and Earth-to-space allocations or in increase in slant path atmospheric attenuation at low elevation angle, e.g. 20°;

   b) any new allocation to the passive services should avoid adding further difficulties for sharing between active services;

c) in order to accommodate future wideband systems, the allocated bands for the active services should not be fragmented into narrow frequency blocks.

4.1.3.1 Method to satisfy the agenda item (radio astronomy)

4.1.3.1.1 Additional exclusive allocations for radio astronomy

No additional exclusive allocations are required for the radio astronomy service.

4.1.3.1.2 Additional radio astronomy allocations in bands shared with terrestrial services

Additional co-primary allocations should be made to the radio astronomy service in bands that are allocated to terrestrial services. Such allocations would impose constraints on terrestrial services only within a limited number of coordination zones worldwide.

Advantages

- Shared allocations with the terrestrial services would permit the radio astronomy service assured access to bands that are required for astronomical research.

Disadvantages

- Coordination with the radio astronomy service would be required at a few sites worldwide, however, the impact of co-primary allocations to the terrestrial services and the RAS above 71 GHz is expected to be limited. Coordination radii should be of the order of 100 km (60 miles), and would affect principally areas that are uninhabited or very sparsely populated.

4.1.3.1.3 Additional radio astronomy allocations in bands shared with satellite services

Radio astronomy could share with some satellite services, that are known not to make use of the bands now, and are not expected to do so for some time, such as the amateur-satellite service. Sharing may also be possible between the RAS and the ISS. Band sharing between the RAS and some satellite services may be possible through coordination.

Advantages

- Shared allocations with some satellite services would permit the radio astronomy service assured access to bands that are required for astronomical research.

Disadvantages

- There may be minor coordination requirements associated with the affected satellite services. Such coordination requirements may be limited by regulatory action, and may consist of no more than providing the orbital elements to radio astronomy stations through some pre-established mechanism.

4.1.3.1.4 Proposed realignment of services between 71 and 275 GHz for radio astronomy

To protect the passive services from unwanted emissions, there is a need to realign the spectrum between 71 and 275 GHz. Satellite downlinks could be moved towards the edges of the transparent atmospheric windows, leaving the middle portion of the windows available to be shared by terrestrial services and wideband RAS receivers. In shifting certain downlink allocations towards the higher opacity edges of the atmospheric windows care should be taken not to put undue burden on the affected services. For observations from ground-based observatories the most important scientific requirements cover bands near the centre of the atmospheric windows, approximately 71-116 GHz, 136-170 GHz and 200-275 GHz. These bands would allow radio astronomers access to many of the most important molecular lines (CO, CS, HCN, HCO^+, SiO, H_2S, etc.) and would also permit observations of wideband continuum radiation, essential for the study of some phenomena, e.g., the Big Bang.

Advantages

- Along with the proposed shared allocations between terrestrial services and radio astronomy, realignment of the spectrum by WRC-2000 would satisfy the agenda item, and would provide the needed spectrum space and protection to the radio astronomy service. In some instances relocation of satellite downlinks may result in allocation in a spectral region with lower atmospheric absorption than the currently allocated band, due to the overall increase in opacity with frequency across the whole 71-275 GHz range. Reallocation may also remove some regulatory constraints, such as No. **S5.149**, from bands allocated to satellite downlinks.

Disadvantages

- In some instances relocation of satellite downlinks may result in an allocation in a spectral region with slightly higher atmospheric absorption than the currently allocated band. It is not advisable to shift downlink allocations to spectral regions of very high opacity. Typical increases of atmospheric attenuation could be 0-2 dB, which may be modest in comparison to variations in opacity due to common changes in atmospheric conditions.

4.1.3.2 Methods to satisfy the agenda item (Passive sensors)

4.1.3.2.1 Requirements in the range 71-275 GHz

§§ a), b) and c) give a three step methodology to satisfy the spaceborne passive sensor requirements in the range 71-275 GHz as given in Table 4-2 of § 4.1.1.3.1.

a) Retention and required protection of spaceborne passive sensors in currently allocated bands in the 71-275 GHz range

Passive sensor primary allocations in the 86-92 GHz, 100-102 GHz, 109.8-111.8 GHz, 114.25-122.25 GHz, 150-151 GHz, 156-158 GHz, 164-167 GHz, 174.8-176.5 GHz, 182-185 GHz, 200-202 GHz, 226-231 GHz, 235-238 GHz, and 250-252 GHz bands are required for future use of passive sensing. The bands 86-92 GHz, 109.8-111.8 GHz, 164-167 GHz, 182-185 GHz, 226-231 GHz and 250-252 GHz are currently adequately protected. Protection of passive sensors currently allocated in the 100-102 GHz, 116-122.25 GHz, 150-151 GHz, 156-158 GHz, 174.8-176.5 GHz, 200-202 GHz and 235-238 GHz bands may require exclusive use by the passive sensors except in bands where sharing with the ISS is feasible. Further studies are necessary to assess to what extent future active services can share with EESS (passive). The 156-158 GHz band may not be required for satellite passive remote sensing after 2018 and this allocation could be removed at that time.

b) Possible removal of current spaceborne passive sensor allocations that are not required for future use

Based on all known requirements, the present passive sensor allocations in the bands 105-109.8 GHz, 111.8-114.25 GHz, 122.25-126 GHz, 167-168 GHz, 174.5-174.8 GHz and 217-226 GHz may not be needed. The band 156-158 GHz is currently planned for use by certain instruments but may not be needed after the year 2018.

c) Possible additional spaceborne passive sensor allocations in the 71-275 GHz range

Additional primary allocations could be made in the following bands in order to satisfy the spaceborne passive sensor spectrum requirements given in Table 4-2 of § 4.1.1.3.1: 148.5-150 GHz and 151-151.5 GHz; 155.5-156 GHz and 158-158.5 GHz (noting that these two bands may not be required after 2018); 176.5-182 GHz and 185-191.8 GHz; 202-209 GHz; and, 230-231.5 GHz. Introduction of passive sensors into these bands may not create favourable sharing situations for any of the affected services. Protection of passive sensors may require initial exclusive allocations in these bands, pending the conduct of sharing studies to establish the extent that future active services can share with EESS (passive).

Advantages

- Maintaining and protecting some of the current spaceborne passive sensor allocations would satisfy some of the passive sensor requirements for current and future applications.
- The additional requirements of passive sensors in the range 71-275 GHz would be satisfied in these key bands which would allow the various meteorological and global change applications to be carried out for now and the future.
- Also removing the current passive sensor allocations that may not be required will allow these bands to be used by active services.

Disadvantages

- In order to adequately protect many of the existing and additional passive sensor allocations and allow for the future growth of the other services that are currently allocated to these bands, these active services would consequentially need to be equitably accommodated in other appropriate bands.

4.1.3.2.2 Additional passive requirements above 275 GHz

Footnote No. **S5.565** of the Table of Frequency Allocations could be modified to reflect the new requirements of the passive services above 275 GHz identified as described in §§ 4.1.1.2.3 and 4.1.1.3.2.

Advantages

- This action would indicate the scientific use of passive services above 275 GHz.

Disadvantages

- There are no disadvantages to this action.

4.1.4 Regulatory and procedural considerations

Any new or relocated allocations would require an updating of the Table of Frequency Allocations contained in Article **S5** as well as a thorough review of all relevant footnotes.

****

4.2 Agenda item 1.17

"to consider possible worldwide allocation for the Earth exploration-satellite (passive) and space research (passive) services in the band 18.6-18.8 GHz taking into account the results of ITU-R studies"

4.2.1 Summary of technical and operational studies

The band 18.6-18.8 GHz is allocated to the EES (passive) and SR (passive) services on a primary basis in Region 2 and on a secondary basis in Regions 1 and 3. The FS, the MS and the FSS (space-to-Earth) are allocated worldwide on a primary basis. Nos. **S5.522** and **S5.523** request administrations to limit the power of fixed-service transmitters and the pfd produced by FSS space stations as far as possible in order to reduce the risk of interference to passive sensors. Simultaneous measurements in several different frequency bands are required to isolate the values of any one surface phenomenon (such as rain or ocean wind speed). Measurements in the 18.6-18.8 GHz band are essential because the band has unique characteristics that are important to obtaining measurements of environmental conditions on the Earth's land and ocean surfaces. This band is also essential to the FSS and FS for telecommunications applications. The FS service uses this band to provide mobile network infrastructure and medium hop links for public telecommunications networks.

A number of studies have been carried out by various administrations leading to the following Recommendations:

Recommendations ITU-R SA.515-3, SA.1028-1, SA.1029-1 and F.761.

4.2.2 Analysis of the results of studies

4.2.2.1 Sharing between EESS (passive) and the GSO FSS

Previous studies have determined that passive spaceborne sensors and GSO FSS networks operating at the pfd limit in the RR would not be compatible.

4.2.2.1.1 Impact of various FSS pfd limits on EESS (passive)

Studies within ITU-R have shown that an FSS pfd limit of -112 dB(W/m^2) across the 200 MHz band 18.6-18.8 GHz would be necessary to enable passive sensors to meet their interference criterion of -155 dBW in a reference bandwidth of 100 MHz (Recommendation ITU-R SA.1029-1) without any constraints on the design of the passive sensors. However, these studies also have shown that with a pfd limit of -101 dB(W/m^2) in a reference bandwidth of 200 MHz, sensor data could be obtained when the sensor moves away from the Equator where the angle between the direction of the reflected GSO FSS signal and the sensor antenna is greatest. Further studies examined the data loss experienced by the passive sensor for a variety of GSO FSS pfd limits ranging from -101 dB(W/m^2) to -82 dB(W/m^2) in a reference bandwidth of 200 MHz. These studies determined the passive sensor data loss for a variety of GSO FSS deployment scenarios for 4, 8 and 16 GSO FSS satellites per GSO FSS coverage area. The results are given in Table 4-3.

TABLE 4-3

Coverage loss for various GSO FSS pfd values

pfd	Data loss over GSO FSS service area			Data loss over all land masses		
dB(W/m^2) 18.6-18.8 GHz	4 satellites	8 satellites	16 satellites	4 satellites	8 satellites	16 satellites
-101			2.4%			2.1%
-100		0.3%	7.8%		0.3%	6.7%
-98	0.3%	3.2%	32.1%	0.3%	2.8%	27.6%
-97	0.8%	7.9%	43.3%	0.7%	6.8%	37.2%
-96	2.0%	16.1%	50.1%	1.7%	13.8%	43.0%
-95	**4.4%**	**26.5%**	**54.5%**	**3.7%**	**22.8%**	**46.9%**
-94	8.6%	36.3%	58.3%	7.4%	31.2%	50.1%
-93	14.9%	43.6%	61.6%	12.8%	37.5%	52.9%
-92	22.9%	48.7%	64.6%	19.7%	41.8%	55.6%
-91	31.5%	52.6%	67.5%	27.0%	45.2%	58.0%
-90	38.9%	56.1%	70.3%	33.5%	48.2%	60.4%
-88	49.4%	62.2%	75.9%	42.5%	53.5%	65.3%
-86	56.7%	68.1%	82.7%	48.8%	58.5%	71.1%
-84	63.1%	74.3%	92.2%	54.2%	63.9%	79.3%
-82	69.4%	82.8%	98.0%	59.7%	71.2%	84.2%

These values were derived with the assumption that the entire world's land masses were all serviced by the same distribution of GSO FSS systems. This is clearly not the case as many areas of the world would require four or less GSO FSS satellites to service a given area while very few areas of the world would require as many as 8 to 16 GSO FSS satellites to meet their communications needs. To take into account this uneven distribution, a four satellite system's average within a given service area on a worldwide basis is considered a reasonable hypothesis. In addition, to limit the data loss by EESS (passive), it is also assumed that the passive sensor will be limited to taking data in only 50% of its orbit (i.e. while travelling towards the poles).

Based on these hypotheses, an FSS pfd limit of -95 dB(W/m^2) per 200 MHz in the 18.6-18.8 GHz band will provide a data loss below 5%, as shown in Table 4-3 (first and fourth columns). This data loss value will still allow passive sensor operations to acquire a satisfactory amount of useful data over land masses on a worldwide basis. It should be noted that this pfd limit represents a 17 dB relaxation of the passive sensor protection criteria as contained in Recommendation ITU-R SA.1029-1. It should also be noted that passive sensors that acquire data exclusively over ocean regions will experience far less data loss than the values shown in Table 4-3 and could therefore acquire data over 100% of their orbits over oceans. Therefore, this pfd limit would protect ocean sensing applications to a higher degree. A higher pfd limit for GSO FSS systems utilizing scanning spot beams may also be possible, given the non-continuous nature of the interference; however further studies are required on this point.

Studies within ITU-R have also indicated that a pfd limit of -95 dB(W/m^2) across the 18.6-18.8 GHz band applied to 12-hours highly elliptical orbit (HEO) FSS systems would also protect the EESS (passive) systems. Furthermore, studies have indicated that low-Earth orbiting (LEO) systems cause significantly greater interference into the sensor than do either GSO or HEO systems. However, these studies did not arrive at an appropriate pfd limit for LEO FSS systems that would protect sensor operations in this band. Therefore, ITU-R should perform studies to determine an appropriate pfd limit for LEO FSS systems that would protect the operation of spaceborne passive sensors and allow satisfactory operation of LEO FSS systems, before such systems are introduced into the 18.6-18.8 GHz band.

4.2.2.1.2 Impact of new pfd constraints on the FSS

The limit of -95 dB(W/m^2) across the 18.6-18.8 GHz band however constitutes a 13 dB tightening on the existing limit which will place constraints on the future development of the GSO FSS in this band. Assuming that spacecraft amplifiers in this band will reach power levels comparable to those in 4/6 GHz and 11/14 GHz bands (21 dBW), for example a spot beam with 50 dBi gain would exceed the limit by at least 3 dB (-92.2 dB(W/m^2)). Prime power and bus size limit the number of such beams that would be present on a GSO spacecraft. However, these beams would have minimal impact on the EESS (passive) as they would be few in number and have a very small footprint on the Earth. As a result, an excessively constraining pfd limit denies the ability of future GSO systems to focus energy in limited geographic areas. From the FSS perspective a viable solution would be to impose a limit of -92 dB(W/m^2) in the 18.6-18.8 GHz band, which would allow for the growth of the GSO FSS.

Table 4-4 illustrates the minimum earth station antenna size which can be used in example systems with clear-sky C/N objectives of 17 dB and 11 dB, for various system noise temperatures and pfd limits. Compared to the current RR pfd limit equivalent to -82 dB(W/m^2) per 200 MHz, a limit of -95 dB(W/m^2) in the 18.6-18.8 GHz band, would substantially restrict the ability of FSS operators to use the band for services to small-dish earth terminals, which are required increasingly today.

TABLE 4-4

Minimum earth station antenna size (metres) without adjacent satellite interference

Clear sky C/N		**11 dB**			**17 dB**		
pfd (dB(W/m^2) per 200 MHz)		**-88**	**-92**	**-95**	**-88**	**-92**	**-95**
System noise temp	300 K	0.13	0.21	0.30	0.27	0.42	0.59
	600 K	0.19	0.30	0.42	0.38	0.59	0.84
	1 000 K	0.24	0.38	0.54	0.48	0.77	1.08

Satellite spacing and interference environment must also be considered. These effects are illustrated in the results from an example analysis shown in Table 4-5 whereby the required earth station antenna size is given that will assure acceptable sharing conditions for GSO satellites at 2° orbital spacing of co-coverage satellites using the same polarization. The analysis assumes a net C/I for the intra-beam interference of 18 dB, as was the case in Annex 2 of Recommendation ITU-R S.1328(Rev.). The receiver noise temperature was conservatively assumed to be 600 K. It also assumes an identical satellite on either side of the desired satellite at 2 degree orbital spacing of co-coverage satellites using the same polarization, which is the worst case. For any desired net C/(N+I) level, the user terminal is then sized to provide the necessary isolation of the adjacent satellites to assure the desired signal quality. For the appropriate D/λ, Recommendations ITU-R S.465-5 and S.580-5 were used to model the earth terminal antenna gain envelope. The analysis was performed for pfd values of -95, -92 and -88 dB(W/m^2) per 200 MHz. Interference from the FS is not considered in this analysis.

TABLE 4-5

Minimum earth station antenna size (metres)
with adjacent satellite interference (2º orbital spacing)

C/(N+I)		**11 dB**			**17 dB**		
pfd (dB(W/m^2) per 200 MHz)		**-88**	**-92**	**-95**	**-88**	**-92**	**-95**
System noise temp	300 K	0.63	0.63	0.64	1.81	1.92	2.09
	600 K	0.63	0.64	0.67	1.89	2.09	2.40
	1 000 K	0.64	0.66	0.77	1.98	2.30	2.75

Recommendation ITU-R S.1328(Rev.) tabulates typical satellite characteristics to be considered in frequency sharing analyses. It includes descriptions for several FSS systems that provide multi-megabit services to terminals 66 cm and smaller with equivalent pfd limits of -101 to -82 dB(W/m^2) per 200 MHz. One example cited provided 92 Mbit/s service to a 66 cm earth station with an equivalent pfd of -101 dB(W/m^2) per 200 MHz. Another example had 120 Mbit/s service to a 66 cm earth station with an equivalent pfd of -98 dB(W/m^2) per 200 MHz, including 2.5 dB of rain margin.

It is therefore feasible to achieve up to 120 Mbit/s data rate into a 66 cm antenna with a pfd of -95 dB(W/m^2) per 200 MHz, assuming a static rain margin of 5.5 dB while accounting for intra-system interference of -18 dB and inter-system interference of -22 dB. Furthermore, increasing the pfd value by 13 dB to -82 dB(W/m^2) per 200 MHz has virtually no effect on either the achievable data rate or required antenna size to assure acceptable sharing in the case of 2 degree orbital spacing of similar GSO FSS systems.

There is an increasing trend today for small-dish applications, but when the total FSS downlink allocation between 17 and 21 GHz is analysed, it is found that the existing allocations to other services or other FSS applications (e.g. bidirectional FSS allocations) are incompatible with small-dish applications at many frequencies. Therefore, the 18.6-18.8 GHz allocation forms a significant part of the total FSS downlink allocation between 17 and 21 GHz, which is available in practice for small-dish earth terminals.

Many planned GSO FSS systems would be compatible with the pfd limit of -95 dB(W/m^2) in the 18.6-18.8 GHz band, but the majority of planned systems may not.

4.2.2.2 Sharing between EESS (passive) and the fixed service

Studies within ITU-R have been performed to analyse the sharing between FS and EESS (passive). Three solutions have been identified that offer a possible sharing situation:

Solution 1: The total input power to an FS antenna across the 200 MHz band 18.6-18.8 GHz is limited to 0 dBW.

Solution 2: The output power from each FS RF carrier frequency at the input of the antenna within the 18.6-18.8 GHz band is limited to -3 dBW. It should be noted that multiple FS RF carrier frequencies individually respecting the above output power limit can be transmitted from a single antenna of an FS system in the 18.6-18.8 GHz band.

Solution 3: The output power from each FS RF carrier frequency at the input of the antenna within the 18.6-18.8 GHz band is limited to 0 dBW. It should be noted that multiple FS RF carrier frequencies individually respecting the above output power limit can be transmitted from a single antenna of an FS system in the 18.6-18.8 GHz band.

Solution 3, put forward recently from the FS as an additional solution, has not been properly analysed from the point of view of EESS (passive) potential additional data losses.

4.2.3 Method to satisfy the agenda item and their advantages and disadvantages

WRC-2000 could consider establishing common worldwide primary allocations for the Earth exploration-satellite (passive) and space research (passive) services. Constraints on the characteristics of GSO FSS and FS systems as well as on the operation of the passive sensors would be required. It would be necessary to:

a) limit the power flux-density produced by a fixed-satellite system at the Earth's surface to a value of -95 dB(W/m^2) across the 18.6-18.8 GHz band, but allow a 3 dB exceedance for 5% of the time everywhere.

Advantage

- This solution permits the Earth exploration-satellite service to operate with acceptable loss of data, and permits the FSS to operate in low and medium rain areas through the use of power control when needed.

Disadvantage

- In order to operate satisfactorily in tropical areas the FSS may need to use earth station antennas up to 50% larger than would otherwise be required.

NOTE - WRC-2000 may require that, as a matter of urgency, ITU-R study the need for a variance in the value of 5% of time associated with FSS systems use of the band 18.6-18.8 GHz band in tropical areas;

b) limit the power delivered to the antenna of a fixed-service station as given in either Solution 1, Solution 2 or Solution 3 of § 4.2.2.2. Additionally FS stations should use transmitting antennas with good radiation patterns taking into account Recommendation ITU-R F.699.

Advantage

- A primary worldwide allocation for EESS would allow passive microwave sensors to obtain critical environmental measurements on a worldwide basis for meteorology and the study of global change of the Earth's environment with some data loss and at the same time it will still allow the orderly development of FS systems in the band.

Disadvantage

- For the sharing between FS and EESS (passive), the three solutions proposed represent possible compromises, but while the EESS data loss in the first two solutions has been thoroughly studied, Solution 3 presents the disadvantage of an additional unknown amount of data loss for the EESS (passive), linked to the difficult prediction of the amount and density of future FS systems in the band.

4.2.4 Regulatory and procedural considerations

If a primary allocation worldwide were to be made to EESS (passive) in the band 18.6-18.8 GHz band, appropriate limits and protection required for FSS, FS, MS and SRS systems in this band would need to be included in the RR.

CHAPTER 5

Appendices S30 and S30A

(WRC-2000 agenda items 1.19, 1.19*bis*, 1.20, 1.21)

CONTENTS

Appendices S30 and S30A

5 Introduction

The World Radiocommunication Conference 1997 (WRC-97) under its agenda item 1.10 revised the Region 1 and 3 downlink and feeder-link Plans. This revision initiated various actions to be carried out either by the Radiocommunication Bureau or by the Radiocommunication Study Groups. These tasks are referred to in the following Resolutions of WRC-97:

a) Resolution **49 (WRC-97)** "Administrative due diligence applicable to some satellite communication services"

b) Resolution **53 (WRC-97)** "Updating the "Remarks" columns in the tables of Article 9A of Appendix **S30A** and Article 11 of Appendix **S30** to the Radio Regulations"

c) Resolution **73 (WRC-97)** "Measures to solve the incompatibility between the broadcasting-satellite service in Region 1 and the fixed-satellite service in Region 3 in the frequency band 12.2-12.5 GHz"

d) Resolution **532 (WRC-97)** "Review and possible revision of the 1997 broadcasting-satellite service Plans for Region 1 and 3"

   WRC-97 in its Resolution **532 (WRC-97)** has resolved that an Inter-Conference Representative Group (IRG) be established to study the feasibility of increasing the minimum number of channels capacity for countries in Region 1 and 3 to an equivalent of around ten analogue channels in accordance with the principles set out in Annex 1 of that Resolution.

e) Resolution **533 (WRC-97)** "Implementation of the decision of the WRC-97 relating to Appendices **S30** and **S30A** to the Radio Regulations"

f) Resolution **534 (WRC-97)** "Implementation of Annex 5 to Appendix **S30** and Annex 3 to Appendix **S30A**"

g) Resolution **536 (WRC-97)** "Operation of broadcasting satellite serving other countries"

h) Resolution **538 (WRC-97)** "Use of the frequency bands covered by Appendices **S30/30** and **S30A/30A** by non-geostationary-satellite systems in the fixed-satellite service"

5.1 Agenda item 1.21

"to consider the report from the Radiocommunication Bureau on results of the analysis in accordance with Resolution **53 (WRC-97)** and take appropriate actions"

5.1.1 Updating of the "Remarks" columns in the tables of Article 9A of Appendix S30A and Article 11 of Appendix S30

Activities relating to the implementation of Resolution **53 (WRC-97)** with respect to the definitive results of the compatibility analysis between the Regions 1 & 3 revised Plans and other services having allocation in the Planned bands in all three Regions have been carried out by the Radiocommunication Bureau based on Notes 3 to 7 in Section 9A.2 of Article 9A of Appendix **S30A** and Notes 5 to 7 in Section 11.2 of Article 11 of Appendix **S30**. The results will be sent to administrations by a Circular Letter no later than early January 2000, at the latest.

****

5.2 Agenda item 1.20

"to consider the issues related to the application of Nos. **S9.8, S9.9** and **S9.17** and the corresponding parts of Appendix **S5** with respect to Appendices **S30** and **S30A**, with a view to possible deletion of Articles 6 and 7 of Appendices **S30** and **S30A**, also taking into consideration Recommendation **35 (WRC-95)**"

5.2.1 Procedures for the use of the guardbands of Appendices S30 and S30A Plans to perform space operations functions

The lack of a coordination procedure and criteria relating to the use of the guardbands of the BSS and associated feeder-link Plans to perform space operation functions was pointed out during WRC-95.

It was noted that the ITU-R had developed criteria that could be used in applying the procedures of Article **S9** or Appendices **S30** and **S30A** in this context. It was concluded that a possible way to apply these procedures in this context would be to coordinate such use using the same procedures as those applicable to non-planned services in the bands covered by these Appendices, specifically:

- to coordinate this use with the assignments subject to the Plan using Article 7 of Appendix **S30** or No. **S9.8** and Article 7 of Appendix **S30A** or No. **S9.9**, as appropriate;
- to coordinate this use with the assignments in non-planned service, and vice-versa, using the provisions of Articles **S9/S11**;
- to coordinate modifications to the Plans with such use using paragraph 4.3.1.5 or 4.3.3.5, as appropriate, of Article 4 of Appendix **S30,** and using paragraph 4.2.3.x of Article 4 of Appendix **S30A** (see section 5.2.3 for details on this possible additional provision).

This approach may be implemented by the inclusion in Article 2 of Appendix **S30** or in a footnote to the titles of Articles **S9** and **S11** of the following provision:

ADD The use of the guardbands of the Plans in Appendix **S30**, as defined in section 3.9 of Annex 5 to this Appendix, to provide space operations functions in accordance with No. **S1.23** shall be coordinated with the assignments subject to these Plans using the provisions of Article 7 of this Appendix/No. **S9.8**. Coordination among assignments intended to provide these functions and services not subject to a Plan shall be effected using the provisions of No. **S9.7** and the associated provisions of Articles **S9** and **S11.** Coordination of modifications to the Plans with assignments intended to provide these functions shall be effected using paragraph 4.3.1.5 or 4.3.3.5, as appropriate, of Article 4 of Appendix **S30.**

and by the addition in Article 2 of Appendix **S30A** or in a footnote to the titles of Articles **S9** and **S11** of the following provision:

ADD The use of the guardbands of the Plans in Appendix **S30A**, as defined in sections 3.1 and 4.1 of Annex 3 to this Appendix, to provide space operations functions in accordance with No. **S1.23** shall be coordinated with the assignments subject to these Plans using the provisions of Article 7 of this Appendix/No. **S9.9**. Coordination among assignments intended to provide these functions and services not subject to a Plan shall be effected using the provisions of No. **S9.7** and the associated provisions of Articles **S9** and **S11**. Coordination of modifications to the Plans with assignments intended to provide these functions shall be effected using paragraph 4.2.3.x of Article 4 of Appendix **S30A**.

The coordination criteria applicable in the above procedures would be equally applicable to the situations involving space operations functions in the guardbands of the Plans. It was noted that the ITU-R had identified an additional criterion, specifically related to this situation, which is still being studied.

5.2.2 Method to determine the need for coordination between assignments in Appendix S30A Plan or in the Plan modification process and non-planned space and terrestrial services

ITU-R concluded that the coordination method currently in section 3 of Annex 4 of Appendix **S30A** should be replaced by Appendix **S7**, in order to provide a consistent protection of non-planned services in respect of the planned and non-planned services in the frequency bands covered by Appendices **S30A**. This would align the situation in this respect to that currently existing between Appendix **S30A** plan and terrestrial services, where the method in Appendix **S7** is already specified in the relevant procedures. This change has been assumed in the following.

5.2.3 Identification of deficiencies in the current procedures of Articles 4, 6 and 7 of Appendices S30 and S30A and Article S9 of the Radio Regulations and possible modifications to these articles to correct these deficiencies

"Some other administrations are of the opinion that Agenda item 1.20 of WRC-2000 is limited to treat Articles 6 and 7 of Appendixes **S30** and **S30A** while protecting the full integrity of the Plans and this should be the sole objective of any proposed revisions to the Radio Regulations. However, the proposed modifications under item 5.2.3, 5.2.3.1, 5.2.3.2, and 5.2.3.2.1 contradict with the above objective. Therefore, this group of administrations does not agree with those proposals as well as with the relevant examples given in this Chapter. Modifications of Articles 6 and 7 of Appendixes **S30** and **S30A** shall in no way introduce limitations to the revision of Regions 1 and 3 Plans by a WRC."

In the framework of Resolution 86 of the Plenipotentiary Conference (Minneapolis, 1998), the current situation of the relevant procedures of Article **S9** and Articles 4, 6 and 7 of Appendices **S30** and **S30A** was analysed with regard to the two following possible principles:

1) all possible cases of interference that may arise in practice between planned BSS and non-planned services (e.g. FSS or FS) should be covered by a procedure;
2) the coordination between earth stations and terrestrial stations, and between earth stations operating in opposite directions of transmission should be undertaken by and between the administrations on the territory of which these stations are located.

The following conclusions were reached. It should be noted that in the following, modifications to the Plans are not considered as part of a non-planned service.

5.2.3.1 Coordination, with unplanned services, of modifications to the BSS Plans before inclusion in the Plans

There is no possibility to include in the coordination process the assignments for which a modification to one of the BSS Plans in Appendices **S30** and **S30A** has been initiated, but not yet completed. This allows non-planned assignments to a space station, an earth station or a terrestrial station to be recorded in the Master Register after successful application of the appropriate procedures of Article **S9** and Appendices **S30/S30A**, and modifications to one of the Appendices **S30/30A** Plans to be recorded in the relevant Plan, whilst these assignments might eventually be incompatible.

As proposed at CPM-97, equitable access to the orbit/spectrum resources between non-planned and planned services would require changes in Articles 6 and 7 of Appendices **S30** and **S30A** or in Appendix **S5** in order to solve this difficulty.

Under Articles 6 and 7 of Appendices **S30/S30A**, a simple solution to this difficulty was proposed at CPM-97, and consists in replacing the terms "assignment in conformity with a Plan", wherever it appears in Articles 6 or 7 of Appendices **S30/S30A**, by the terms "assignment in conformity with the appropriate Regional Plan or for which the corresponding Plan modification procedure has been initiated".

No modification would be required under Nos. **S9.8**, **S9.9** or **S9.17A**, but under Appendix **S5**, a similar change would be required to include in the coordination process the assignments for which Article 4 of Appendices **S30/S30A** has been initiated.

It was however noted that such modification and coupling between FSS and BSS publications would increase the workload of the Bureau and possibly lead to a backlog since examination of new FSS publications will require treatment by the Bureau of all modifications to the appropriate BSS Plan already submitted and vice versa.

5.2.3.2 Coordination between earth stations and terrestrial stations, and between earth stations operating in opposite directions of transmission

The coordination between earth stations and terrestrial stations, and between earth stations operating in opposite directions of transmission should normally be handled between the administrations on the territory of which these stations are located. This general principle is set forth in Resolution **1 (Rev.WRC-97)**, which *resolves* that "that, unless specifically stipulated otherwise by special arrangements communicated to the Union by administrations, any notification of a frequency assignment to a station shall be made by the administration of the country on whose territory the station is located". This was probably the intention of WARC-77 and RARC-83 in that it was not foreseen that the administration with the space station, which is the one applying the procedure of modification of the Plan, might one day be different from the one with the earth station. The fact that these two administrations could be different is now creating problems of principle, including those relating to sovereign rights.

5.2.3.2.1 Coordination between BSS receive earth stations and transmit terrestrial stations

a) Current situation under Appendix S30 with respect to national territory

Protection of receive BSS earth stations associated to successful modifications of the Plan is ensured by Article 6 of Appendix **S30** and its associated method for determining the need for a coordination in Annex 3 of Appendix **S30** (i.e. pfd limit at the edge of the BSS service area).

This allows an administration to request protection for its BSS receive earth stations in all the planned BSS frequency band and anywhere in its territory. A view was expressed that this may entail inequitable access to the spectrum resources between planned and non-planned services since the future terrestrial stations located near the edge of the service area will have to protect these BSS receive earth stations irrespective of the time of their deployment and their location. Nevertheless, it is recognized that if an administration is providing BSS over its territory, it is appropriate to seek full protection for existing and future BSS receive earth stations.

Pending modifications to the Plans are not protected from terrestrial stations until they become a part of the Plans, which can be a lengthy process (see section 5.2.3.1).

No. **S9.19** provides a regulatory approach similar to that of Article 6 of Appendix **S30** in that the protection of the BSS service area is ensured by a coordination process (No. **S9.19**) triggered by a pfd limit at the edge of the service area.

No. **S9.19** may therefore be considered as a possible replacement of Article 6 of Appendix **S30**, with the inclusion in Appendix **S5** of the coordination trigger currently included in Annex 3 of Appendix **S30**.

b) Difficulties with the current procedures

Coordination under Article 6 of Appendix **S30** is currently sought with the administration which applied the procedure of modification of the Plan which may not be the administration on whose territory the receive BSS earth stations are located. Potential solutions to this difficulty are identified in section d).

In addition, the protection of receive BSS earth stations associated to a proposed modification of the Plan is not covered by the current procedures since Article 4 of Appendix **S30** does not allow the proposed modification of the Plan to seek protection from terrestrial service. This issue is addressed in section c).

c) Procedure to seek protection of modifications to the Plan from terrestrial services

The protection of receive BSS earth stations associated to a modification of the Plan - whether this modification was successfully applied or not - could be sought by the administration on the territory of which these earth stations are located through the application of No. **S9.17**, which is now possible under the Radio Regulations which provisionally entered into force on 1 January 1999. However, this approach has the consequence of the responsible administration having to coordinate and notify a potentially large number of BSS receive earth stations, which has implications for the administration and the Bureau.

In BSS, receive earth stations are deployed ubiquitously over the service area and the BSS operator or administration on which territory the BSS earth stations are located does not know the location of these ubiquitous earth stations.

Since notification of BSS receive earth stations is not possible with the current Article **S11**, a possible solution to seek the coordination of BSS receive earth stations could be to use the same criteria applying to typical mobile earth stations (i.e. to determine the coordination area which would encompass all coordination areas determined for each location in the service area within which operation of the BSS receive earth stations is proposed). Alternatively, Article 4 could be modified to include an additional provision enabling an administration proposing a modification to the Plans to seek protection for the service area from terrestrial services.

d) Case of service areas exceeding national territory

The coordination between transmit terrestrial stations and receive BSS earth stations (in planned bands or unplanned bands) is a bilateral matter between the administrations concerned. In the case of the BSS service area covering territory other than that of the space station administration, the notifying administration of the space station is not involved. In the eventual case of harmful interference, it is also a matter for the administrations concerned. Another approach to this issue would be to recognize in the RR the bilateral nature of this matter and delete Article 6 of Appendix **S30** or change it to cover the multinational aspect of this issue.

It was noted that section 1.1 of Annex 5 of Appendix **S30** provided the following definition of the service area: "the area on the surface of the Earth in which the administration responsible for the service has the right to demand that the agreed protection conditions be provided". It was also noted that in the case of a BSS covering the territory of administrations other than that of the administration responsible for the BSS space station, this definition causes some problems.

It was also noted that the Rule of Procedure on No. **S23.13** stated that in case of agreement under No. **S23.13**, it is understood that there is no objection to the inclusion of the territory in the planned service area.

A possible solution to protect the complete service area could be as follows:

1) the notifying administration or BR list by the country symbol those territories to be included in the proposed service area (the agreement should be sought in accordance with paragraph 2.1 of the existing Rules of Procedure concerning No. **S23.13**);
2) any administration that does not object to being in the service area within a period of four months is considered to be in the service area in order to be protected from transmitting terrestrial stations;
3) in order to protect this service area from future transmitting terrestrial stations, Article 6 of Appendix **S30** with the appropriate amendments would be used with respect to this service area and this would be applied by the administration of the terrestrial stations and the concerned administration for the protected service area.

e) Possible options to resolve the difficulties identified

Based on these considerations, five options were identified to cover the coordination between receive BSS earth stations and transmit terrestrial stations:

- Option A - under this option, protection of a modification to the Plan would be ensured over the entire service area as soon as the modification is entered in the Plan, using the criterion of Annex 3 of Appendix **S30** and the procedure of Article 6 of Appendix **S30**/No. **S9.19**.
- Option B - this option would be the same as option A, but protection would be extended from the date of receipt of the request for modification by the BR.
- Option C - this option would be the same as option A, but Article 6 of Appendix **S30** would be deleted and this coordination would be left to the administrations on the territories of which the BSS earth stations and terrestrial stations are located.
- Option D - under this option, protection would have to be sought through the application of No. **S9.17**, using the criterion of Annex 3 or Appendix **S7,** from the date of entry in the Plan of the modification.
- Option E - this option would be the same as option D, but protection would be extended from the date of receipt of the request for modification by the BR.

It was noted that the implications of options D and E could result in the requirement to coordinate and notify a very large number of BSS receive earth stations.

Annexes 1 and 2 provide example regulatory text reflecting options A and B.

Some administrations are of the view that they are obliged to coordinate their terrestrial stations in respect to BSS earth stations only when the country concerned has a BSS assignment appearing in the Plan or in the MIFR on its behalf.

5.2.3.2.2 Coordination between BSS receive earth stations and FSS transmit earth stations operating in opposite directions of transmission

The protection of receive BSS earth stations associated to a proposed modification to the Plan from FSS transmit earth stations operating in opposite directions of transmission (e.g. in the frequency band 12.5-12.7 GHz which is allocated to planned BSS in Region 2 and to FSS Earth-to-space in Region 1) could be sought by the administration on the territory of which these earth stations are located, through the application of No. **S9.17A**, which is now possible under the Radio Regulations which provisionally entered into force on 1 January 1999.

Another solution would be to retain Article 6 of Appendix **S30** with the necessary modifications.

In this case, as stated in Appendix **S5**, coordination will be required when the coordination area of the FSS transmit earth station will cover the territory of the administration within which the receive BSS earth stations are located.

The five options discussed in the previous section also apply in this situation.

5.2.3.2.3 Coordination between planned transmit BSS feeder-link earth stations and receive terrestrial stations

Coordination of transmit BSS feeder-link earth stations associated to a modification of the Plan with receive terrestrial stations (i.e. in the bands 14.5-14.8 GHz and 17.7-18.1 GHz in Regions 1 and 3, and in the band 17.7-17.8 GHz in Region 2) is currently sought by the administration which applied the procedure of modification of the Plan and which may not be the administration on whose territory these earth stations will be operated. In addition, the current procedure requires a global service area coordination (i.e. with typical BSS feeder-link earth stations) which is generally impossible to achieve.

In order to conform with Resolution **1 (Rev.WRC-97)**, such coordination could be limited to a case-by-case coordination undertaken by the appropriate administrations with the specific transmit BSS feeder-link earth stations located on their own territory, which has proven its efficiency throughout the years in the case of coordination between FSS earth stations and terrestrial stations.

A solution could consist in replacing paragraphs 4.2.1.3 and 4.2.3.3 of Article 4 of Appendix **S30A** by No. **S9.17** and by suppressing Article 6 of Appendix **S30A**. Another solution would be to retain Article 6 with the necessary modifications.

5.2.3.2.4 Coordination between planned transmit BSS feeder-link earth stations and FSS receive earth stations operating in opposite directions of transmission

As for the interference cases described in the previous sections, this type of coordination should normally be handled between the administrations on the territory of which these earth stations are located. In the same way as identified in section 5.2.3.2.3, procedures under 4.2.1.2/4.2.3.2 of Article 4 of Appendix **S30A** and section 7.2 of Article 7 of Appendix **S30A** could be replaced by No. **S9.17A**. Another solution would be to retain Article 7 with the necessary modifications.

5.2.3.2.5 Coordination of typical BSS or BSS feeder-link earth stations with terrestrial stations or earth stations operating in the opposite direction of transmission

It was noted that the current procedures of Appendices **S30** and **S30A** considered, for the coordination of BSS or BSS feeder-link earth stations with terrestrial stations or earth stations operating in the opposite direction of transmission, under Articles 4, 6 and 7 of these appendices, the whole BSS or BSS feeder-link service area:

- under Article 6 of Appendix **S30**, the criterion used in Annex 3 of Appendix **S30** is intended to protect the whole BSS service area from interference caused by terrestrial stations;
- under Articles 4 and 6 of Appendix **S30A** and under Sections 7.2 to 7.7 of Article 7 of Appendix **S30A**, the BSS feeder-link administration seeks and is entitled to protect any point of the service area from constraints relating to sharing with terrestrial stations or earth stations operating in the opposite direction of transmission.

It was noted that this situation allowed a modification to a Plan to benefit from protection rights vis-à-vis terrestrial services and earth stations operating in the opposite direction of transmission, without having acquired these rights through the application of a procedure.

The replacement of the provisions by **S9.17**, **S9.17A** and **S9.18** may lead to a more equitably balanced situation between the services involved in such a sharing situation, since the latter provisions are applicable only to specific earth stations. The possibility of extending these provisions to typical earth stations using modifications of the Plans, whilst ensuring equitable access to spectrum by all the services involved, requires further studies. It should be noted that five options have been identified to address this situation (see section 5.2.3.2.1).

It should be noted that possible solutions to this problem are likely to differ for Appendices **S30** and **S30A**, since the location of feeder-link earth stations is generally known in advance.

5.2.3.3 Interference situations not covered in the current regulations

5.2.3.3.1 Protection of Appendix S30 Region 2 Plan from non-planned BSS in Region 3

The coordination of planned BSS with non-planned BSS (i.e. in the frequency band 12.5-12.7 GHz, where BSS is planned in Region 2 and non-planned in Region 3) is covered in Article 4 of Appendix **S30** (4.3.3.6), but the reciprocal case is not covered in Article 7 of Appendix **S30** or in Article **S9**. This allows non-planned BSS assignments to be recorded in the Master Register after successful application of No. **S9.7** and Resolution **33 (Rev.WRC-97)**, whilst these assignments could affect BSS assignments in the Appendix **S30** Region 2 Plan or in the Plan modification process.

A regulatory solution to this difficulty was proposed at CPM-97, and included in the CPM Report to WRC-97. It consists in replacing the terms "fixed-satellite service" by "fixed-satellite service or broadcasting-satellite service where these services are not subject to a Plan", in Article 7 of Appendix **S30** or in No. **S9.8** and Appendix **S5**. Criteria of Annex 4 of Appendix **S30** could be used to determine if the coordination is required.

5.2.3.3.2 Coordination between non-planned BSS feeder links and modifications to BSS feeder-link Plan in the 17.8-18.1 GHz band

The current procedures do not provide for any coordination process between the BSS feeder-link assignments in Appendix **S30A** or their modifications and the non-planned FSS (Earth-to-space), i.e. non-planned BSS feeder links in Region 2 in the frequency band 17.8-18.1 GHz. This allows non-planned BSS feeder-link assignments in Region 2 to be recorded in the Master Register after successful application of No. **S9.7**, whilst these assignments could affect, or be affected by BSS feeder-link assignments in Appendix **S30A** in Regions 1 and 3, or in the Plan modification process. Symmetrically, this allows modifications to the feeder-link Plan in Region 1 and 3 to be included in this Plan without any coordination with non-planned Region 2 BSS feeder links, whilst the latter might be affected or might affect the former.

A solution to this difficulty was proposed at CPM-97 and included in the CPM Report to WRC-97. It involves:

- under Article 4 of Appendix **S30A**, the inclusion of an additional paragraph in order to protect Region 2 non-planned FSS (Earth-to-space) from modifications to the Region 1 and 3 feeder-link Plan;
- in Article 7 of Appendix **S30A**, the replacement of "FSS (space-to-Earth)" by "FSS" in order to protect Regions 1 and 3 feeder-link Plan from non-planned BSS in Region 2;
- in No. **S9.9**, the suppression of the term "space", before "station in the FSS", in such a way that the procedure would cover the interference caused by either an FSS space station or an FSS earth station, and the need to exclude **S9.17A** from the scope of **S9.9** (as currently done under **S9.7**).

In both cases, the criteria to determine if the coordination is required could be the same as between the feeder-link Plans, i.e. the criteria of section 5 of Annex 1 to Appendix **S30A**. However this requires further study.

5.2.3.3.3 Protection of planned BSS receive space stations from non-planned Region 2 BSS transmit space stations in the band 17.3 to 17.8 GHz

Non-planned BSS transmit space stations in the frequency band 17.3-17.8 GHz may apply section 7.1 of Article 7 of Appendix **S30A**, but No. **S9.9** currently does not cover this possibility. This could be done simply by replacing the words "station in the FSS" in No. **S9.9** by "station in the FSS or in the BSS".

5.2.3.3.4 Protection of non-planned BSS receive earth stations in Region 2 from modifications to BSS feeder-link Plan in the band 17.3 to 17.8 GHz

The protection of non-planned BSS receive earth stations in Region 2 in the band 17.3-17.8 GHz from modifications to one of the Plans in Appendix **S30A** is not covered by Article 4 of Appendix **S30A**, and the reciprocal situation is not covered either under section 7.2 of Article 7 of Appendix **S30A**, or under No. **S9.17A**. This could be solved simply by replacing in these provisions (either section 7.2 of Article 7 or No. **S9.17A**) the word "FSS" by "FSS or unplanned BSS".

The same difficulty identified under section 5.2.3.2.1 with respect to the coordination of typical BSS receive earth stations, i.e. the criteria to be used for seeking the coordination, is also applied to non-planned BSS receive earth stations.

5.2.3.3.5 Scope of footnotes S5.487 and S5.490

Footnotes **S5.487** for Regions 1 and 3, and **S5.490** for Region 2, appear to provide a super-primary status to the broadcasting-satellite service over the other primary services sharing the same band (FSS, BS, FS), in that they require the latter services not to cause harmful interference to broadcasting-satellite stations operating in accordance with the provisions of Appendix **S30**. These footnotes are also the subject of a Rule of Procedure, which concludes that, if, despite the application of the procedures of Appendix **S30**, harmful interference is actually caused to a broadcasting-satellite station, the station in the other service shall cease this interference.

It is understood by some administrations that these footnotes were adopted in order to ensure the protection of the assignments that were foreseen to be included in Appendix **S30** Plans by WARC -7 and RARC-83/WARC-Orb-85 against interference caused by assignments in other services which existed prior to the entry into force of these Plans, i.e. to avoid restrictions on the elaboration of the original Plans, as shown in the initial versions of these footnotes, adopted respectively by WARC-71 and WARC-79. One view was expressed that these restrictions apply only to the original Plans; another view considered that they apply to the Plans as they may be modified.

No. S5.43 states that where it is indicated in these Regulations that a service may operate in a specific frequency band subject to not causing harmful interference, this means also that this service cannot claim protection from harmful interference caused by other services to which the band is allocated under Chapter **SII** of these Regulations. It appears that this provision should not apply in the context of sharing between the primary services allocated in the frequency band covered by Appendix **S30**.

One view noted was that since assignments in other services received by the Bureau after the establishment of the Plans have to apply the procedures of Appendix **S30** to protect the Plans, the intent of No. **S5.487** and No. **S5.490** may be understood as covered by these procedures. For these reasons one conclusion which could be drawn is that modifications to the Plans cannot be considered as benefiting from the protection of **S5.487** and **S.5.490.**

Another view noted was that sections 4.3.17 of Appendix **S30** and 4.2.18 of Appendix **S30A** indicate that frequency assignments that enter the Plans through the modification procedure shall enjoy the same status as those appearing in the appropriate Regional Plan and will be considered as a frequency assignment in conformity with the Plan. Thus, application of footnotes **S5.487** and **S5.490** may be understood as applying to modifications successfully entered into the Plans.

Therefore, the application of footnotes **S5.487** and **S5.490** to modifications to the Plans which are in conformity with these plans may need further clarification.

5.2.3.4 Example of additions/modifications to the Radio Regulations to resolve identified difficulties/inconsistencies

In order to facilitate the understanding of these proposals, attached Figures 5.1 to 5.4 provide a summary of the current procedures and an example of possible additions/modifications.

In these figures, the arrows indicate that the coordination is requested to the party in the direction of which the arrow is pointing. A code is used to identify coordination provisions taking place between the administrations with the space stations (thick boxes), between an administration with a space station and an administration with terrestrial stations (thin boxes) or between administrations with terrestrial or earth stations (dotted boxes). In the two first cases, coordination follows a publication by the Bureau. In the latter case, it is to be undertaken directly by the administrations on the territory of which the stations are located, without publication by the Bureau.

Annex 1 contains possible examples of modifications to the current provisions in Article **S9**, Appendices **S30** and **S30A** that might reflect the various options identified above in the case where Articles 6 and 7 of Appendix **S30** and **S30A** would be retained and the currently suspended provision Nos. **S9.8** and **S9.9** would be suppressed (Approach A).

Annex 2 contains possible examples of modifications to the current provisions in Article **S9**, Appendices **S30** and **S30A** that might reflect the various options identified above in the case where Articles 6 and 7 of Appendix **S30** would be suppressed and replaced by provision Nos. **S9.8** and

S9.18 and Articles 6 and 7 of Appendix **S30A** would be suppressed and replaced by provision Nos. **S9.9**, **S9.17A** and **S9.18** (Approach B).

A third Approach (Approach C) was identified based on separating the modifications to the Plans from the original Plans. This Approach may avoid most of these deficiencies since they appear to arise from the fact that a modification to a Plan is proposed by the space station administration (which may be different from the administration on the territory of which the BSS receive earth stations are located) and, once a modification is included in the Plan, it benefits from the same rights as any assignment included in the Plan by a conference (with the exception of the time-limit to bring the assignment in service) whilst these rights may not have been coordinated with the services and administrations involved. This Approach requires further study.

5.2.3.5 Protection of the terrestrial service from modifications to the Appendix S30 BSS Plans

Annex 1 to Appendix **S30** of the Radio Regulations specifies limits for determining whether a service is affected by a proposed modification to the Plan and therefore it is necessary to seek the agreement of any other administration. Section 5 of Annex 1 specifies limits to the change in the power flux-density to protect the terrestrial services from modifications to the Region 2 BSS Plans. In addition, section 8 a) applies parts of section 5 to modifications to the Regions 1 and 3 BSS Plans.

ITU-R studied possible modification to the pfd limits in sections 5 b) and 5 c) of Annex 1. Section 5 c) specifies limits for determining whether terrestrial services of administrations in Region 1 east of longitude 30°E. in the 12.2-12.7 GHz band may be affected by modifications to the Region 2 BSS Plan.

Relaxation of the pfd limits in section 5 c) would facilitate BSS to certain geographical areas in Region 2. BSS transmit power to certain portions of Region 2 immediately adjacent to portions of Region 1 must be significantly reduced in order to meet the specified levels in the section 5c) pfd limit. These lower power levels necessitate the use of much larger BSS receive antennas than other Region 2 areas.

The pfd limits in section 5 b) determine if terrestrial services in Region 1 west of 30º E. and all of Region 3 may be affected by modifications to the Region 2 BSS Plan, or determine if terrestrial services in Regions 1 and 3 may be affected by modifications to the Regions 1 and 3 BSS Plan (see section 8 a) of Annex 1 to Appendix **S30**).

After reviewing various proposals, ITU-R found that the following proposal represented a good compromise package to replace the current pfd limits in both sections 5 b) and 5 c) of Annex 1:

-148 dB(W/m^2/4 kHz)	for	$0^\circ \leq \gamma < 5^\circ$
$-148 + 0.5(\gamma - 5)$ dB(W/m^2/4 kHz)	for	$5^\circ \leq \gamma < 25^\circ$
-138 dB(W/m^2/4 kHz)	for	$25^\circ \leq \gamma < 90^\circ$

These pfd limits are currently contained in Table **S21-4** of Article **S21** for the protection of the FS from the FSS in the 12 GHz bands. These limits are more relaxed than the current limits in sections 5 b) and 5 c) at low arrival angles and thus meet the expressed concerns of the BSS community. On the other hand, they are more stringent at higher arrival angles than section 5 c) thus providing greater protection to the terrestrial services. Therefore these limits represent a compromise between the various requirements in the band. Furthermore the Article **S21** limits have been successfully applied for a long time to protect terrestrial services from the FSS.

Additionally, modification to these pfd limits may facilitate the revision of the Regions 1 and 3 Plans (under WRC-2000 agenda item 1.19 and Resolution **532 (WRC-97)**).

Administrations are encouraged to review all of the pfd limits in sections 4, 5 and 8 of Annex 1, which provide limits to determine if terrestrial services in the various regions may be affected by modifications to the BSS Plans, for possible modification or consolidation, with a view to establishing an equitable balance of constraints between the three Regions.

ANNEX 1 TO CHAPTER 5

Example of possible modifications to Articles S9, Appendix S5 and Articles 4, 6 and 7 of Appendices S30 and S30A to update these appendices in relation to non-planned services under the assumption that Articles 6 and 7 of these appendices are retained in these appendices

("APPROACH A")

Sub-Section IIA – Requirement and request for coordination

Some administrations expressed the view that modifications to the Plans should be protected from the date of receipt of the modification request at BR. This would be achieved by replacing the words "assignment in conformity with a Plan" in Articles 6 and 7 of Appendices **S30** and **S30A** by "assignment in conformity with the appropriate Regional Plan or for which the corresponding Plan modification procedure has been initiated".

Other administrations expressed the view that such a change is not covered by agenda item 1.20, that these provisions were originally drafted to protect the Plans from modifications and from other services, and therefore that such a change would be inappropriate and should not be considered as a deficiency.

To highlight this issue, the phrase assignments "in conformity with appropriate Regional Plan" has been placed in square brackets throughout this Annex.

NOC S9.6 to S9.7

SUP S9.8

SUP S9.9

NOC S9.10 to S9.16

MOD **S9.17** *f)*~~[13]~~ for any specific earth station or typical mobile earth station in frequency bands above 1 GHz allocated with equal rights to space and terrestrial services, in respect of terrestrial stations, where the coordination area of the earth station includes the territory of another country, with the exception of the coordination under No. **S9.15**, Article 4 of Appendix **S30A** and BSS receive earth stations associated with assignments subject to the Appendix **S30** Plans;

MOD **S9.17A** *g)* for any specific earth station, in respect of other earth stations operating in the opposite direction of transmission, in frequency bands allocated with equal rights to space radiocommunication services in both directions of transmission and where the coordination area of the earth station includes the territory of another country or the earth station is located within the coordination area of another earth station, with the exception of the ~~frequency bands subject to the~~coordination under Article 6 of Appendix **S30**, Article 7 of Appendix **S30A** ~~Plans~~and **S9.19**;

MOD **S9.18** *h)* for any [transmitting station] of a terrestrial service in the bands referred to in No. **S9.17** within the coordination area of an earth station, in respect of this earth station, with the exception of the coordination under Nos. **S9.16**, ~~and~~ **S9.19** and Article 6 of Appendix **S30**;

MOD **S9.19** *i)* for any transmitting station of a terrestrial service or a transmitting earth station in the fixed-satellite service (Earth-to-space) in a frequency band shared on an equal primary basis with the broadcasting-satellite service, with respect to an earth station of the broadcasting-satellite service, except where this service is subject to the Appendix **S30** Plans;

NOC **S9.20 to S9.31**

MOD **S9.32** If the responsible administration concludes that coordination is not required under No~~s~~. **S9.7** ~~to **S9.9**~~, it shall send the relevant information pursuant to Appendix **S4** to the Bureau for action under No. **S9.34**.

NOC **S9.32A to S9.40A**

~~[13] **S9.17.1** Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.~~

MOD S9.41 Following receipt of the Weekly Circular referring to requests for coordination under No~~s~~. **S9.7** ~~to **S9.9**~~, an administration believing that it should have been included in the request shall, within four months of the date of the relevant Weekly Circular, inform the initiating administration and the Bureau, giving its technical reasons for doing so, and shall request that its name be included.

NOC S9.42 to S9.44

Sub-Section IIB – Acknowledgement of receipt of a request for coordination

NOC S9.45 to S9.49

Sub-Section IIC – Action upon a request for coordination

MOD S9.51 Following its action under No. **S9.50**, the administration with which coordination was sought under No~~s~~. **S9.7** ~~to **S9.9**~~ shall, within four months of the date of publication of the Weekly Circular under No. **S9.38**, either inform the requesting administration and the Bureau of its agreement or act under No. **S9.52**.

NOC S9.51A to S9.59

Sub-Section IID – Action in the event of no reply, no decision or disagreement on a request for coordination

MOD S9.60 If, within the same four-month period specified in Nos. **S9.51** or **S9.51A**, an administration with which coordination is sought under No~~s~~. **S9.7** ~~to **S9.9**~~ and **S9.15** to **S9.19** fails to reply or to give a decision under Nos. **S9.51** or **S9.51A** or, following its disagreement under No. **S9.52**, fails to provide information concerning its own assignments on which its disagreement is based, the requesting administration may seek the assistance of the Bureau.

Notification, examination and recording in the Master International Frequency Register of frequency assignments to space stations in the broadcasting-satellite service

MOD

ARTICLE 6

Coordination, notification and recording in the Master International Frequency Register of frequency assignments to terrestrial stations or to earth stations in the fixed-satellite service (Earth-to-space) affecting broadcasting-satellite frequency assignments in the frequency bands 11.7-12.2 GHz (in Region 3), 11.7-12.5 GHz (in Region 1) and 12.2-12.7 GHz (in Region 2)[5]

Section I – Coordination procedure to be applied

MOD 6.1.1 Before notifying to the Bureau a frequency assignment to a terrestrial transmitting station or to a transmitting earth station in the fixed-satellite service, an administration shall initiate coordination with any other administration having a frequency assignment to a broadcasting-satellite station in [conformity with the appropriate Regional Plan] if:

– the necessary bandwidths of the two transmissions overlap; *and*

– the power flux-density which would be produced by the proposed terrestrial transmitting station or by the transmitting earth station in the fixed-satellite service exceeds the value derived in accordance with Annex 3 at one or more points on the edge of the service area which is within the coverage area of the broadcasting-satellite station of that administration.

MOD **6.1.2** For the purpose of effecting coordination, the administration responsible for the terrestrial station or for the earth station in the fixed-satellite service shall send to the administrations concerned, by the fastest possible means, a diagram drawn to an appropriate scale indicating the location of the terrestrial station or the earth station in the fixed-satellite service and all other data of the proposed frequency assignment and the approximate date on which it is planned to bring the station into use.

NOC **6.1.3 to 6.1.9**

MOD **6.1.10** Where an administration fails to reply within one month of dispatch of the Bureau's telegram sent under § 6.1.7 requesting an acknowledgement or fails to give a decision on the matter within two months of dispatch of the Bureau's telegram of request sent under § 6.1.8, the administration with which coordination was sought shall be considered to have undertaken that no complaint will be made in respect of any harmful interference which may be caused by the terrestrial station or by the earth station in the fixed-satellite service being coordinated to the service rendered or to be rendered by its satellite-broadcasting station.

NOC **6.1.11 to 6.1.12**

Section II – Notification procedure for frequency assignments

MOD **6.2.1** Any frequency assignment to a fixed, land or broadcasting station or to an earth station in the fixed-satellite service shall be notified to the Bureau if the use of the frequency concerned is capable of causing harmful interference to the service rendered or to be rendered by a broadcasting-satellite station of any other administration, or if it is desired to obtain international recognition of the use of the frequency[7].

MOD **6.2.2** For this notification, an individual notice for each frequency assignment shall be drawn up as prescribed in Appendix **S4**, Annexes 1A and 1B, or Annexes 2A and 2B, as appropriate, which specifies the basic characteristics to be furnished as required. It is recommended that the notifying administration should also supply the additional data called for in that Appendix, together with such further data as it may consider appropriate.

NOC **6.2.3 to 6.2.4**

---

[7] The attention of administrations is specifically drawn to the provisions of Section I of this Article.

Section III – Procedure for the examination of notices and the recording of frequency assignments in the Master Register

MOD 6.3.1 Whatever the means of communication, including telegram, by which a notice is transmitted to the Bureau, it shall be considered complete if it contains at least the appropriate basic characteristics specified in Appendix **S4**, Annexes 1A and 1B or Annexes 2A and 2B, as appropriate.

NOC 6.3.2 to 6.3.32

6.3.33 Change in the basic characteristics of assignments already recorded in the Master Register

MOD 6.3.34 Any notice of a change in the basic characteristics of an assignment already recorded in the Master Register, as specified in Appendix **S4**, Annexes 1A and 1B or Annexes 2A and 2B, as appropriate (except those entered in Columns 2c, 3 and 4a of the Master Register), shall be examined by the Bureau in accordance with the provisions of § 6.3.8 and 6.3.9 and, where appropriate, § 6.3.10 and the provisions of § 6.3.12 to 6.3.32 inclusive shall be applied. Where the change should be recorded, the original assignment shall be amended according to the notice.

NOC 6.3.35 to 6.3.41

MOD

Procedures for coordination, notification and recording in the Master International Frequency Register of frequency assignments to stations in the fixed-satellite service (space-to-Earth) in the frequency bands 11.7-12.2 GHz (in Region 2), 12.2-12.7 GHz (in Region 3) and 12.5-12.7 GHz (in Region 1), and to stations in the broadcasting-satellite service in the frequency band 12.5-12.7 GHz (in Region 3) when frequency assignments to broadcasting-satellite stations [in conformity with the Regions 1 and 3 Plan, or the Region 2 Plan] are involved[8]

MOD **Section I – Procedure for the advance publication of information on planned fixed-satellite (space-to-Earth) or broadcasting-satellite~~fixed-satellite~~ systems**

Publication of information

MOD 7.1.1 An administration which intends to establish a ~~fixed~~ fixed satellite or broadcasting-satellite system not subject to a Plan shall, prior to the procedure described in § 7.2.1, where applicable, send to the Bureau, not earlier than five years and preferably not later than two years before the date of bringing into service each satellite network of the planned system, the information listed in Appendix **S4**, Annexes 2A and 2B.

NOC 7.1.2 to 7.1.3.1

Comments on published information

MOD 7.1.4 If, after studying the information published under § 7.1.3, any administration is of the opinion that interference which may be unacceptable may be caused to its frequency assignments in [conformity with the appropriate Regional Plan], it shall, within ~~three~~ four months after the date of the Weekly Circular publishing the information listed in Appendix **S4**, Annexes 2A and 2B, send its comments to the administration concerned. A copy of these comments shall also be sent to the Bureau. If no such comments are received from an administration within the period mentioned above, it may be assumed that that administration has no basic objections to the planned fixed-satellite or broadcasting-satellite~~fixed-satellite~~ network(s) of that system of which details have been published.

Resolution of difficulties

NOC 7.1.5 to 7.1.6

Results of advance publication

NOC 7.1.7

Commencement of coordination or notification procedure

MOD 7.1.8 In complying with the provisions of § 7.1.5 and 7.1.6, an administration responsible for a planned fixed-satellite system in the fixed-satellite service, or in the broadcasting-satellite service not subject to a Plan shall, if necessary, defer its commencement of the coordination procedure of § 7.2.1 or, where this is not applicable, the sending of its notices to the Bureau until six ~~five~~ months after the date of the Weekly Circular containing the information listed in Appendix **S4**, Annexes 2A and 2B on the relevant satellite network. However, in respect of those administrations with which difficulties have been resolved or which have responded favourably, the coordination procedure, where applicable, may be commenced prior to the expiry of the ~~five~~ six-months mentioned above.

Section II – Coordination procedures to be applied in appropriate cases

MOD 7.2.1 Before an administration notifies to the Bureau or brings into use any frequency assignment to a space station in the fixed-satellite service (space-to-Earth), or in the broadcasting-satellite service-not subject to a Plan, it shall seek the agreement of any other administration having a frequency assignment [in conformity with the appropriate Regional Plan], if:

a) any portion of the necessary bandwidth proposed for the space station in the fixed-satellite or broadcasting-satellite~~fixed-satellite~~ service falls within the necessary bandwidth associated with the frequency assignment to the broadcasting-satellite station; *and*

b) the power flux-density which would be produced by the proposed fixed-satellite or broadcasting-satellite~~fixed-satellite~~ assignment exceeds the value specified in Annex 4.

For this purpose, the administration seeking agreement shall send to any other such administration the information listed in Appendix **S4**, Annexes 2A and 2B.

NOTE - The last paragraph of section 7.2.1 should be reviewed in order to align this Article with the current practice for non-planned services, where this information is only sent to the Bureau.

NOC 7.2.2

MOD 7.2.3 An administration seeking coordination under § 7.2.1 shall at the same time send to the Bureau a copy of the request for coordination together with the information listed in Appendix **S4**, Annexes 2A and 2B and the name(s) of the administration(s) whose agreement is sought. The Bureau shall determine on the basis of Annex 4 which frequency assignments [in conformity with the appropriate Regional Plan] are considered to be affected. The Bureau shall include the names of those administrations with the information received from the administration seeking coordination and shall publish this information in a special section of its Weekly Circular, together with a reference to the Weekly Circular in which details of the satellite system were published in accordance with Section I of this Article. When the Weekly Circular contains such information, the Bureau shall so inform all administrations by circular telegram.

NOTE - This paragraph should be reviewed in order to align this Article with the current practice for non-planned services, where this information is only sent to the Bureau.

NOC 7.2.4 to 7.2.13

Section III – Notification of frequency assignments

MOD 7.3.1 Any frequency assignment to a space station in the fixed-satellite or in the broadcasting-satellite~~fixed-satellite~~ service not subject to a Plan shall be notified to the Bureau:

a) if the use of the frequency concerned is capable of causing harmful interference to a frequency assignment of another administration which is [in conformity with the appropriate Regional Plan][10]; *or*

b) if it is desired to obtain international recognition of the use of the frequency.

NOC 7.3.2 to 7.3.5

Section IV – Procedure for the examination of notices and the recording of frequency assignments in the Master Register

NOC 7.4.1 to 7.4.5.1

MOD 7.4.5.2 where appropriate, with respect to its conformity with the provisions of § 7.2.1, relating to the coordination of the use of the frequency assignment with the other administrations concerned having a frequency assignment [in conformity with the appropriate Regional Plan];

---

[10] The attention of administrations is specifically drawn to the application of § 7.2.1 above.

MOD 7.4.5.3 where appropriate, with respect to the probability of harmful interference to the service rendered or to be rendered by a broadcasting-satellite station whose frequency assignment is [in conformity with the appropriate Regional Plan].

NOC 7.4.6 to 7.4.9

MOD 7.4.9.1 Where the Bureau finds that the coordination procedures mentioned in § 7.4.5.2 have been successfully completed with all administrations whose frequency assignments [in conformity with the appropriate Regional Plan] may be affected, the frequency assignment shall be recorded in the Master Register. The date of receipt by the Bureau of the notice shall be entered in Column 2d.

NOC 7.4.9.2 to 7.4.9.3

MOD 7.4.9.4 Where the notifying administration resubmits the notice and the Bureau finds that the coordination procedure mentioned in § 7.4.5.2 has been successfully completed with all administrations whose frequency assignments [in conformity with the appropriate Regional Plan] may be affected, the frequency assignment shall be recorded in the Master Register. The date of receipt of the original notice by the Bureau shall be entered in Column 2d. The date of receipt by the Bureau of the resubmitted notice shall be entered in the Remarks Column.

NOC 7.4.9.5 to 7.4.12

MOD 7.4.12.1 A notice of a change in the basic characteristics of an assignment in the fixed-satellite or broadcasting-satellite not subject to a Plan~~fixed-satellite~~ service already recorded, as specified in Appendix **S4**, Annexes 2A and 2B (except the name of the station or the name of the locality in which it is situated or the date of bringing into use), shall be examined by the Bureau in conformity with § 7.4.5.1 and, where appropriate, § 7.4.5.2 and 7.4.5.3, and the provisions of § 7.4.7 to 7.4.11.3 inclusive shall apply. Where the change should be recorded, the original assignment shall be amended accordingly.

NOC 7.4.12.2 to 7.4.12.4

MOD 7.4.13 Recording of frequency assignments in the fixed-satellite or broadcasting-satellite not subject to a Plan~~fixed-satellite~~ service notified before being brought into use

NOC 7.4.13.1 to 7.4.13.3

Section V – Recording of findings in the Master Register

NOC 7.5

Section VI – Categories of frequency assignments

NOC 7.6.1 to 7.6.3

Section VII – Review of findings

NOC 7.7.1 to 7.7.4

Section VIII – Modification, cancellation and review of entries in the Master Register

NOC 7.8

MOD 7.8.1 Where the use of a recorded assignment to a station in the fixed-satellite or broadcasting-satellite service not subject to a Plan~~fixed-satellite service~~ is suspended for a period of eighteen months, the notifying administration shall, within this eighteen-month period, inform the Bureau of the date on which such use was suspended and of the date on which the assignment is to be brought back into regular use.

MOD 7.8.2 Whenever it appears to the Bureau, whether or not as a result of action under § 7.8.1, that a recorded assignment to a space station in the fixed-satellite or broadcasting-satellite service not subject to a Plan~~fixed-satellite service~~ has not been in regular use for more than eighteen months, the Bureau shall inquire of the notifying administration as to when the assignment is to be brought back into regular use.

MOD 7.8.3 If no reply is received within six months of action by the Bureau under § 7.8.2, or if the reply does not confirm that the assignment to a space station in the fixed-satellite or broadcasting-satellite service not subject to a Plan~~fixed-satellite service~~ is to be brought back into regular use within this six-month limit, a mark should be entered against the entry in the Master Register.

NOTE - This section should be reviewed in order to be aligned with the current practice as contained in **S11.49**.

NOC 7.8.4 to 7.8.6

ANNEX 4

MOD

Need for coordination of a transmitting space station in the fixed-satellite service or in the broadcasting-satellite service where this service is not subject to a Plan: in Region 2 (11.7-12.2 GHz) with respect to the Regions 1 and 3 Plan, in Region 1 (12.5-12.7 GHz) and in Region 3 (12.2-12.7 GHz) with respect to the Region 2 Plan

(See Article 7)

NOC

With respect to § 7.2.1 of Article 7, coordination of a space station in the fixed-satellite service of Region 2 is required when, under assumed free-space propagation conditions, the power flux-density on the territory of an administration in Region 1 or Region 3 exceeds the value derived from the expressions given below.

MOD

With respect to § 7.2.1 of Article 7, coordination of a space station in the fixed-satellite service (space-to-Earth) in Region 1 or 3 or broadcasting-satellite service not subject to a Plan in Region 3 is required when, under assumed free-space propagation conditions, the power flux-density on the territory of an administration in Region 2 exceeds the value derived from the same expressions:

-147 dB(W/m^2/27 MHz)	for	$0° \leq \theta < 0.44°$;
$-138 + 25 \log \theta$ dB(W/m^2/27 MHz)	for	$0.44° \leq \theta < 19.1°$;
-106 dB(W/m^2/27 MHz)	for	$\theta \geq 19.1°$;

MOD

where θ is:

– the difference in degrees between the longitude of the interfering fixed-satellite space station in Region 2 and the longitude of the affected broadcasting-satellite space station in Regions 1 and 3, *or*

– the difference in degrees between the longitude of the interfering fixed-satellite space station in Region 1 or 3 or the interfering broadcasting-satellite space station in Region 3 and the longitude of the affected broadcasting-satellite space station in Region 2.

APPENDIX S30A

ARTICLE 4

Procedure for modifications to the Plans

NOC 4.1 to 4.2.1.1

NOC 4.2 **Proposed modifications to a frequency assignment in conformity with one of the Regional Plans or proposed inclusion in that Plan of a new frequency assignment**

For Regions 1 and 3

NOC 4.2.1 An administration proposing a modification to the characteristics of a frequency assignment in conformity with the Regions 1 and 3 Plan or the inclusion of a new frequency assignment in that Plan shall seek the agreement of those administrations:

NOC 4.2.1.1

SUP 4.2.1.2 ~~having a frequency assignment in the band 17.7-18.1 GHz to an earth station in the fixed-satellite service (space-to-Earth), which is recorded in the Master Register or which has been coordinated or is being coordinated under the provisions of No. **S9.7** and which is located within the coordination area of the feeder-link fixed-satellite earth station; *or*~~

ADD 4.2.1.2 of Region 2 having a feeder-link frequency assignment in the fixed-satellite service (Earth-to-space) in the band 17.8-18.1 GHz in the same channel or an adjacent channel, which is recorded in the Master Register or which has been coordinated or is being coordinated under the provisions of No. **S9.7** and the associated provisions under Articles **S9** and **S11** or paragraph 7.1 of Article 7 of Appendix **S30A**; *or*

SUP 4.2.1.3

NOC 4.2.1.4

NOC 4.2.1.5

NOC 4.2.1.6

NOC 4.2.2

For Region 2

NOC 4.2.3

NOC 4.2.3.1

SUP 4.2.3.2

SUP 4.2.3.3

NOC 4.2.3.4 to 4.42

NOTE - Other approaches enabling to keep the above provisions may be possible, but require further studies in order to enable them to be applied by the administration on the territory of which the feeder-link earth station is located. The view was expressed that the above modifications may limit the flexibility of administrations to deploy feeder-link earth stations.

ANNEX 1

Limits for determining whether a service of an administration is considered to be affected by a proposed modification to one of the regional Plans or when it is necessary under this Appendix to seek the agreement of any other administration

SUP 1

SUP 2

NOC 3 to 5

NOTE - The view was expressed that the above modifications may limit the flexibility of administrations to deploy feeder-link earth stations.

ADD 6 Limits applicable to protect a frequency assignment in the bands 17.8-18.1 GHz (Region 2) to a receiving space station in the fixed-satellite service (Earth-to-space)

An administration in Region 2 shall be considered affected by a proposed modification in Region 1 and 3 when the power flux-density arriving at the receiving space station of a broadcasting-satellite feeder-link station would cause an increase in the noise temperature of the feeder-link space station which exceeds the threshold value of $\Delta T/T$ corresponding to [3%], where $\Delta T/T$ is calculated in accordance with the method given in Appendix **S8**, except that the maximum power densities per hertz averaged over the worst 1 MHz are replaced by power densities per hertz averaged over the total RF bandwidth of the feeder-link carriers.

Reasons: Protect non-planned BSS feeder links in Region 2 from modifications to the feeder-link Plan in Regions 1 and 3.

NOTE - The applicability of 3% ΔT/T criterion for the protection of unplanned feeder links requires further study.

ARTICLE 5

Coordination, notification, examination and recording in the Master International Frequency Register of frequency assignments to feeder-link transmitting earth stations and receiving space stations in the fixed-satellite service

NOC 5.1 to 5.1.3

ADD 5.1.3A Before an administration notifies to the Bureau or brings into use any frequency assignment to a transmitting feeder-link earth station located on its territory in the bands 14.5-14.8 GHz and 17.3-18.1 GHz which has been included in the relevant Plan after successful application of the procedure of Article 4 of this Appendix, it shall effect coordination of this assignment under the provisions of Nos. **S9.17, S9.17A** and **S9.19** with the other administrations whose terrestrial stations or earth stations operating in the opposite direction of transmission, as appropriate, might be affected by this assignment.

NOC 5.1.4 to 5.3.2

NOTE - Other approaches which would enable the avoidance of applying other provisions outside of this Appendix may be possible, but require further studies in order to enable them to be applied by the administration on the territory of which the feeder-link earth station is located. The view was expressed that the above modifications may limit the flexibility of administrations to deploy feeder-link earth stations.

NOC ARTICLE 6

MOD

ARTICLE 7

Procedure concerning coordination, notification and recording in the Master International Frequency Register of frequency assignments to stations~~-~~in the fixed-satellite service (space-to-Eearth) in Regions 1~~,~~ 2 and 3 in the band 17.7-18.1 GHz~~ and in Region 2 in the band 17.7-17.8 GHz~~, to stations~~-~~in the fixed-satellite service (Earth-to-space) in Region 2 in the band 17.8-18.1 GHz and to stations in the broadcasting-satellite service in Region 2 in the band 17.3-17.8 GHz, when frequency assignments to feeder links for broadcasting-satellite stations ~~appearing~~ subject to ~~in~~ the Regions 1 and 3 Plan or the Region 2 Plan are involved

MOD 7.1 The provisions of No. **S9.7** and the associated provisions under Articles **S9** and **S11** and Appendi~~x~~ces **S5** and **S8** are applicable to transmitting space stations in the fixed-satellite service in the band 17.7-18.1 GHz, to transmitting earth stations in the fixed-satellite service in Region 2 in the band 17.8-18.1 GHz and the provisions of Resolution 33 **(Rev.WRC-97)** are applicable to transmitting space stations in the broadcasting-satellite service in Region 2 in the band 17.3-17.8 GHz together with the provisions of Annex 4, except that in relation to feeder-link stations, the relevant criteria mentioned in Appendix **S8** are replaced by those given in Section 1 of Annex 4.

MOD 7.2 The provisions of No. **S9.17A** and the associated provisions under Articles **S9** and **S11** and Appendices **S5** and **S7** are applicable to receiving earth stations in the fixed-satellite service and in the broadcasting-satellite service that might be affected by assignments in one of the Plans in Appendix **S30A** or for which the corresponding Plan modification process has been initiated, from the date of receipt of the complete information under paragraph 4.2.5 of Article 4 of this Appendix[5].~~Administrations planning to implement assignments for receiving earth stations in Regions 1 and 3 in the 17.7-18.1 GHz band and in Region 2 in the 17.7-17.8 GHz band in the fixed-satellite service (space-to-Earth) should evaluate the level of interference, assessed on the basis of coordination contours calculated in accordance with Section 3 of Annex 4, which might be caused by the closest feeder-link earth station which could be located on the border of the territory of another administration. Should the administration planning receiving earth stations find that interference may be caused by such a feeder-link earth station, it may request the administration responsible for the feeder-link earth stations to indicate the geographical coordinates, the antenna characteristics and the elevation angle of the horizon around its actual and planned feeder-link earth stations.~~

MOD 7.3 In the case of Region 2, when the entry in the Plan contains information on specific earth stations this shall be used in the interference calculations relating to the application of No. **S9.17A** or **S9.19** as appropriate mentioned in § 7.2 above. When such information is not contained in the Plan an administration which receives a request under **S9.29**~~§ 7.2~~ shall, within a period of ~~three~~four months, communicate the details of the feeder-link earth stations to the administration planning the receiving earth station, and to the Bureau in order to update the Plan.

SUP 7.4

SUP 7.5

SUP 7.6

SUP 7.7

NOTE - The implication of the suppression of the provisions of this section requires further study.

ANNEX 4

Criteria for sharing between services

NOC Section 1

ADD **2 Threshold values for determining when coordination is required between transmitting feeder link earth stations in the fixed-satellite service in Region 2 and a receiving space station in the feeder-link Plans in the frequency bands 17.8-18.1 GHz**

With respect to § 7.1, Article 7 of this Appendix, coordination of a transmitting feeder-link earth station in the fixed-satellite service with a receiving space station in a broadcasting-satellite feeder link in the Regions 1 and 3 Plan or the Region 2 Plan is required, when the power flux-density arriving at the receiving space station of a broadcasting-satellite feeder-link station of another administration would cause an increase in the noise temperature of the feeder-link space station which exceeds a threshold value of $\Delta T/T$ corresponding to 3%, where $\Delta T/T$ is calculated in accordance with the method given in Appendix **S8**.

ANNEX 2 TO CHAPTER 5

Example of possible modifications to Article S9 and Appendix S5 to resolve the deficiencies in Articles [4], 6 and 7 of Appendices S30 and S30A in relation to non-planned services under the assumption that Articles 6 and 7 of these appendices are suppressed

("APPROACH B")

On the basis of the potential solutions described in section 5.3.3 above to correct the deficiencies identified in the current procedures of Article **S9** and Appendices **S30** and **S30A** in relation to the coordination between planned and non-planned services, this Annex contains examples of possible regulatory text that would reflect these solutions by modifications or additions to the current provisions of Article **S9** and Appendix **S5**, and in Appendices **S30** and **S30A**. It assumes that Articles 6 and 7 of Appendices **S30** and **S30A** are suppressed ("Approach B").

EXAMPLE MODIFICATIONS TO ARTICLE S9

Sub-Section IIA – Requirement and request for coordination

NOC S9.6 to S9.7

MOD S9.8 *b)*~~[12]~~ for a transmitting space station ~~of the fixed-satellite service~~ using the geostationary-satellite orbit, in the fixed-satellite service or in the broadcasting-satellite service, in a frequency band and in a Region where this service is not subject to a plan, ~~shared on an equal primary basis with the broadcasting-satellite service,~~ in respect of stations in the broadcasting-satellite service ~~of the latter service~~ which are subject to the Appendix **S30** Plans;

Reasons: Cover the case of non-planned BSS interfering into the Plan or its modifications. This provision would replace Article 7 of Appendix **S30.**

MOD S9.9 *c)*~~[12]~~ for a transmitting ~~space~~ station ~~of~~ in the fixed-satellite service or in the broadcasting-satellite service using the geostationary-satellite orbit in a frequency band and in a Region where this service is not subject to a Plan, ~~shared on an equal primary basis with~~ in respect of a receiving feeder-link space station for ~~the feeder links of~~ the broadcasting-satellite service which is ~~are~~ subject to the Appendix **S30A** Plans;

Reasons: Cover the case of interference into Appendix **S30A** Plan from non-planned BSS in Region 2 (17.3-17.8 GHz) and from feeder links in Region 2 (17.8-18.1 GHz). This provision would replace section 7.1 of Article 7 of Appendix **S30A.**

~~[12] **S9.8.1** and **S9.9.1** Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.~~

NOC **S9.10 to S9.16** Not used.

MOD **S9.17** *f)*[13] for any specific earth station or typical mobile earth station in frequency bands above 1 GHz allocated with equal rights to space and terrestrial services, in respect of terrestrial stations, where the coordination area of the earth station includes the territory of another country, with the exception of the coordination under No. **S9.15**;

MOD **S9.17A** *g)* for any specific earth station, in respect of other earth stations operating in the opposite direction of transmission, in frequency bands allocated with equal rights to space radiocommunication services in both directions of transmission and where the coordination area of the earth station includes the territory of another country or the earth station is located within the coordination area of another earth station~~, with the exception of the frequency bands subject to the Appendix S30A Plans~~ with the exception of coordination under **S9.19**;

Reasons: This coordination must be undertaken by the administration on the territory of which the earth station is located, which is not the case in Article 4 or in Article 7 of Appendix **S30A**. The words deleted were introduced by WRC-97 in order to avoid any unintended consequences. Their suppression would allow to replace both Nos. 4.2.1.2/4.2.3.2 of Article 4 of Appendix **S30A** and section 7.2 of Article 7 of Appendix **S30A**.

NOC **S9.18**

MOD **S9.19** *i)* for any transmitting station of a terrestrial service or a transmitting earth station in the fixed-satellite service (Earth-to-space) in a frequency band shared on an equal primary basis with the broadcasting-satellite service, with respect to an earth station of the broadcasting-satellite service.~~, except where this service is subject to the Appendix S30 Plans;~~

EXAMPLE MODIFICATIONS TO APPENDIX S5

Identification of administrations with which coordination is to be effected or agreement sought under the provisions of Article S9

NOC **1*a)* to 1*e)***

---

[13] ~~**S9.17.1** Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.~~

MOD 1*f)* where appropriate, in conformity with a world or regional allotment or assignment plan and the associated provisions and whose characteristics appear in the relevant Plan as adopted by a world or regional radiocommunication conference; or

ADD 1*f)bis* for which the procedure of Article 4 of Appendix **S30** or Article 4 of Appendix **S30A** has been [initiated or] successfully completed, with effect from the date of receipt by the Bureau of the complete relevant information as specified in Appendix **S4**/Annex 2 or

Some administrations expressed the view that modifications to the Plans should be protected from the date of receipt of the modification request at BR. This would be achieved by removing the square brackets around "initiated or" in ADD 1*f)bis* above.

Other administrations expressed the view that such a change is not covered by agenda item 1.20, that these provisions were originally drafted to protect the Plans from modifications and from other services, and therefore that such a change would be inappropriate and should not be considered as a deficiency.

To highlight this issue, the phrase "initiated or" has been placed in square brackets.

Reasons: Protect modifications of the Plan by a reciprocal coordination from the date the Plan modification process is initiated and, where applicable, from the date the **S9.17** or **S9.17A** procedure has been initiated

NOC **1*g)* to 6**

5.3 Agenda item 1.19

"to consider the report of the inter-conference representative group (IRG) submitted by the Director of the Radiocommunication Bureau and determine the basis for replanning by the next conference so as to afford each country an amount of spectrum that permits the economical development of a broadcasting-satellite service system"

5.3.1 Progress report on ITU-R studies requested by the IRG

Activities relating to the implementation of Resolution **532** (**WRC-97**) have been carried out by IRG and the Group of Technical Experts. The results of the studies will be submitted by the Director Radiocommunication Bureau to WRC-2000.

5.3.1.1 Appropriate technical criteria for compatibility analysis between BSS carriers

5.3.1.1.1 Interference protection masks

ITU-R has developed a draft revision of Recommendation ITU-R BO.1293 concerning protection masks and associated calculation methods for interference into broadcast-satellite systems involving digital emissions.

Following the GTE request to investigate, as a matter of urgency, to give more precise indications on the application of the general default values to be used for the implementation of the draft revised Recommendation ITU-R BO.1293. ITU-R reconfirmed that the general default values, as currently contained in Appendix 1 to Annex 1 of the draft revised Recommendation ITU-R BO.1293, can be applied to all Regions and communicated to the IRG. However, the IRG has not yet dealt with this matter. Moreover, the ITU-R confirmed the appropriateness of the application of the worse case approach to deal with interference from analogue assignments of the Plans into both analogue and digital assignments.

5.3.1.1.2 Interference protection ratio

ITU-R confirmed the protection ratio adopted by WRC-97 for the protection between analogue assignments of the plans, as well as for the protection of digital assignments against interference from analogue assignments, and proposed a new overall co-channel protection ratio value of 20 dB (i.e. 21 dB and 27 dB for downlink and feeder link respectively for "planned digital assignments"). However, further studies are still required to reduce the WRC-97 protection ratios in the case of the protection of digital assignments against interference from analogue assignments.

5.3.1.2 Applicability of Annex 7 limitations

5.3.1.2.1 8 dB e.i.r.p. reduction

ITU-R concluded that the 8 dB reduction in Annex 7 of Appendix **S30** is no longer necessary with respect to terrestrial service.

5.3.1.2.2 Scope of Annex 7 orbital limitation for review

ITU-R will conduct technical studies on the orbital limitations of paragraph A3 of Annex 7, which apply to proposed new BSS assignments in the orbital arc from 37° W to 10° E and adopted a set of preliminary guidelines for conducting studies with respect to these limitations. ITU-R has prepared further studies on this issue which have been sent to the IRG.

5.3.1.3 Channel configuration

ITU-R concluded that the technical implication of a channel configuration (spacing and bandwidth) mostly pertain to the availability of protection criteria and interference calculation methods (draft revision of Recommendation ITU-R BO.1293) that would apply for the new channel configuration.

ITU-R concluded that the draft revised Recommendation ITU-R BO.1293 facilitates the analyses of interference involving channel bandwidths larger than the reference bandwidth of 27 MHz. This has been communicated to the IRG.

5.3.1.4 Sharing criteria to be used for inter-service and interregional compatibility analysis

For its examination of the compatibility between BSS plan assignments and other services, ITU-R has been requested to review the existing sharing criteria of Annex 1, 4 and 6 of Appendix **S30** and Annex 1 and 4 of Appendix **S30A** in terms of their applicability to digital BSS carriers which are going to be used for the planning studies. ITU-R has carried out further studies the results of which have been sent to the IRG.

5.3.1.5 Fast roll-off antennas for BSS space stations

A draft new Recommendation ITU-R BO.[Doc. 11/116] contains (in its Annex 1) new fast roll-off antenna patterns to be used if necessary for the transmitting satellite antenna. This Recommendation presents updated co- and cross-polarization patterns for 12 GHz BSS satellite transmit antennas with fast roll-off characteristics. The new patterns reflect the technical progress and assure that any angle from the centre of the beam, the performance of the fast roll-off antenna exceeds or at least equals that of the "normal" satellite transmit antenna, which is not the case for the patterns currently content in Annex 1 of Appendix **S30**, § 3.1.3.3.

Draft new Recommendation ITU-R BO.[Doc. 11/116], on improved fast roll-off patterns for the space station transmitting antenna, gives cross-polarization performances which are considered feasible and adequate for elliptical beams.

However, composite beams are likely to be implemented by shaped beam techniques, which may only achieve such cross-polarization performances if not combined with fast roll-off co-polar patterns.

Consequently, ITU-R can not, at least for the time being, recommend to apply the draft new Recommendation ITU-R BO.[Doc. 11/116] in case of composite beams. This has been communicated to the IRG.

5.3.1.6 Coordination between co-located BSS and FSS satellites

ITU-R studies indicated that when conducting planning studies in relation to Appendix **S30A**, the criteria of Annex 4 of Appendix **S30A** could be used in order to ensure that existing and planed systems in the FSS and in the BSS are not aversely impacted by modifications in the orbital positions of Appendix **S30A** Plan. Moreover it was suggested that consideration might be given to a

$\Delta T/T$ of 6% in lieu of the 4% level currently appearing in Annex 4 of Appendix **S30A** together with the revised receiver system noise temperature of 600 K instead of 900 K.

5.3.1.7 Sharing with space operation functions in the guardbands of Appendices S30/S30A Plans

In the case where different channel spacings or bandwidths are used in the planning studies, there is a need to study the sharing situation between assignments of Appendices **S30/S30A** Plans and space operation service for BSS space stations only operating in the guardbands of these Plans. ITU-R is developing a Recommendation on coordination procedure for assignments of space operation service in the guardbands of Appendices **S30** and **S30A** Plans.

It was also noted that in accordance with No. 3.9.2 of Annex 5 of Appendix **S30**, the guardbands were intended to protect the services in the adjacent frequency bands.

5.4 Agenda item 1.19*bis*

"in accordance with Article **S14**, to consider objections expressed by administrations with respect to the Radio Regulations Board's Rule of Procedure relating to the application of No. **S23.13/2674** in order for the Bureau to modify its findings in accordance with the conclusions of the conference"

No. **S23.13/2674** states:

"§ 4 In devising the characteristics of a space station in the broadcasting-satellite service, all technical means available shall be used to reduce, to the maximum, the radiation over the territory of other countries unless an agreement has been previously reached with such countries."

In response to Resolution **531 (WRC-95)**, the RRB established a Rule of Procedure in 1996 which was later modified in 1998. If the service area of a BSS system exceeds the territory of the notifying administration, the Rule of Procedure requires that a separate agreement from the one required under Article 4 of Appendix **S30** or Resolution **33 (Rev.WRC-97)** be sought either directly from the administrations concerned or through the publication required under Resolution **33 (Rev. WRC-97)** or the plan modification procedure.

Some administrations consider that this Rule of Procedure should be applied retroactively to systems received by the BR for the application of Article 4 of Appendix **S30** before 18 November 1995. Other administrations consider that such a retroactive application of the Rule would not be appropriate.

5.5 Direct-to-home transmission/broadcasting-satellite service

The IRG requested the ITU-R to provide relevant advice (if any) on the proposal made by several countries at WRC-97 and which was deferred to it by WRC-97, i.e. to include in WRC-01 agenda the "review of the possibility of combining the direct-to-home transmission services by satellite and satellite-broadcasting services in the planned and non-planned bands and its implication on the relevant Articles of the Radio Regulations".

Although no contributions were received on this issue by the time of CPM99-2 (Geneva, 15-26 November 1999), the concerns expressed by some administrations on this issue were noted, however IRG has the prime responsibility for this issue.

CHAPTER 6

Fixed and fixed-satellite services

(WRC-2000 agenda items 1.4, 1.5, 1.8, 1.12 and 1.14)

CONTENTS

Fixed and fixed-satellite services

6.1 Agenda item 1.4

"to consider issues concerning allocations and regulatory aspects related to Resolutions **126 (WRC-97)**, **128 (WRC-97)**, **129 (WRC-97)**, **133 (WRC-97)**, **134 (WRC-97)** and **726 (WRC-97)**"

The texts below are organized according to frequency ranges and topics rather than in the order of appearance of the Resolution numbers in the agenda item.

6.1.1 Resolution 126 (WRC-97) "Use of the frequency band 31.8-33.4 GHz for high-density systems in the fixed service"

The entire band 31.8-33.4 GHz is allocated on a primary basis to the RNS, the 31.8-32.3 GHz band to the SRS (deep space, space-to-Earth) and the 32-33 GHz band to the ISS. The date, as detailed in Resolution **126(WRC-97)**, of the provisional application of the allocation 31.8-33.4 GHz to the FS is 1 January 2001. No. **S5.547** identifies the band as available for High-Density applications in the FS (HDFS).

ITU-R is requested to conduct the appropriate studies to determine what criteria would be necessary for sharing between stations in the FS and stations in the other services to which all or parts of the frequency band 31.8-33.4 GHz are allocated.

6.1.1.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

6.1.1.1.1 High-density applications in the fixed service (HDFS)

The terme "High-Density applications in the Fixed Service (HDFS)" describes a significant level of deployment of point-to-point (P-P) and/or point-to-multipoint (P-MP) systems within a given area. In the bands above 30 GHz, propagation conditions, availability of small, light-weight components and a high degree of frequency reuse are key factors in enabling the deployment of a large population of FS systems.

a) General characteristics of HDFS

High-Density applications are generally characterized as follows:

- operate on a point-to-point or point-to-multipoint basis, or a combination of both;
- flexible, rapid deployment;
- high frequency reuse
- decreased antenna and terminal size with increased frequency;
- should not to be subject to major cost implications due to the need to include mitigation techniques to solve inter-service sharing problems;
- ubiquitous deployment of HDFS stations;
- a wider range of antenna elevation angles than is found at lower bands.

The term HDFS does not refer to a particular application, subservice or band in the fixed service, but does describe the use of maximized density and frequency reuse in the fixed service that are realized through concentrated deployments. Often these deployment density, spectrum reuse and spectral efficiency factors become more pronounced in the higher bands due to correspondingly more favourable conditions for a high deployment of FS stations.

Existing and future HDFS systems include some applications that are deployed without requiring individual frequency assignment for each system. These cases can be summarized under two main headings:

– Area licensing

  Where an operator is assigned a discrete channel or frequency block within a given area within which the operator has full flexibility to deploy systems.

– "Licence exempt"

  Where an administration has identified a band for "licence exempt" use, where systems may use any channel within the band without requiring an individual licence.

Known current high-density systems and usage in the FS include narrow-band wireless access and broadband applications ranging in bands up to 66 GHz. It is likely that HDFS applications will also become operational above 66 GHz.

Competitive access network stations in urban and industrial areas are placed in exposed locations, such as on top of high rise buildings in many cases, which reduces the use of natural or man-made shielding, impacting inter- and intra-service interference in these areas. The use of sectoral or omnidirectional antennas in the hub stations of P-MP systems can be more restrictive to inter- and intra-service coordination, by reducing the benefits of angle discrimination, as compared to point-to-point antennas.

b) New FS technologies for systems above 30 GHz

A number of technologies are in existence or emerging for use in bands above 30 GHz. Recent developments, such as Monolithic Microwave Integrated Circuits (MMIC), have made bands above 20 GHz, particularly in the range 20 to 60 GHz, suitable for these FS applications. Commercial components and devices are available in the market for mass production of affordable equipment.

To further increase spectral efficiency and service flexibility, advanced HDFS systems are likely to employ various techniques that may include different duplex technologies (e.g. FDD and TDD) and dynamic allocation of bit rate, modulation, and antenna beamwidth.

Some HDFS systems will have the functional capability of variable or flexible channelization. This differs from the historical approach in microwave radio systems where fixed channel separation and pre-assigned radio channel centre frequencies have been used. Variable channelization will permit transmission of variable data rates, making it possible to provide a variety of symmetrical or asymmetrical services, based on the needs, an important factor in the growth of wireless services.

c) Planned applications of HDFS

The bands above 30 GHz provide for a high level frequency reuse due to the propagation conditions. Accordingly, high population of FS systems can be achieved in these frequency bands. Consequently the systems in these bands are well suited to increase infrastructure in concentrated population areas. Service bit rates up to 310 Mbit/s are anticipated. Main applications include:

- deployment of mobile network infrastructure for existing and new systems;
- fixed wireless access;
  - accommodate new telecommunication operators in competitive markets;
  - provide alternate technologies for upgrade of existing telephone infrastructure;
  - provide greater access and service choices for residential and commercial users for telephony, data and multimedia services;

- applications requiring no individual frequency assignments possibly in the bands around 60 GHz.

Considering the above applications, potential sharing conditions in the various bands need to be taken into account.

d) Type of systems and system characteristics

The 31.8-33.4 GHz band could accommodate the application of P-P and/or P-MP systems. It offers propagation advantages when considering FS systems in bands above 30 GHz. As a result it will be possible to achieve longer hop lengths which can assist an economical deployment in more dispersed market areas and also to employ high capacity trunk links in dense areas. These characteristics are more pronounced in tropical regions of the world, with high rain precipitation rates, like ITU-R rain zones N and P. In such high rain precipitation regions, HDFS systems operating above 40 GHz will have severe limitations on allowable hop lengths, making difficult its deployment in many applications envisaged. In addition this band provides 1 600 MHz of contiguous spectrum which is ideal for the delivery of broadband services through P-P and P-MP systems. System characteristics for HDFS systems using the frequency band 31.8-33.4 GHz are available in Recommendation ITU-R F.758-1 for P-P and P-MP systems.

Rain outage events are the primary cause of unavailability in this band. Applications typically have to meet availability demands of 99.99% to 99.999% per year. The criteria will be defined individually depending on the importance of the transmitted traffic, respective service, by each operator and the classification within the reference path according to the relevant ITU-T and ITU-R recommendations.

Hop lengths up to about 14 km for P-P systems and for P-MP systems up to 7 km depending on availability criteria, rain zone and transmission capacity are possible.

The following Recommendations have been considered in the studies:

Recommendations ITU-R F.697, F.755, F.758, F.1189, F.1102, F.1400, and ITU-T Recommendations G.821, G.826 and G.827.

6.1.1.1.2 Sharing between the HDFS and other services

A number of preliminary studies have been carried out by various administrations. These studies were based on aggregating the emissions of many HDFS transmitting stations over a large population centre into a single equivalent transmitting station. This simplifying method further assumes that the propagation conditions from stations dispersed over an area to a distant earth station are comparable to the conditions from a single equivalent point to the earth station. Further study is required by ITU-R to validate the above assumptions and to provide guidance on how to account for anomalous propagation conditions for small percentages of time between a population of HDFS transmitting stations and a distant earth station.

The latest versions of Recommendations ITU-R F.758, F.699, F.1245, F.1336, F.1097, F.1333, SA.1157, SA.509, SA.609, IS.847, P.452, P.618, P.620, P.676, RA.769 and SA.1029 are relevant to these studies.

a) HDFS/inter-satellite service (ISS)

Currently no ISS systems are implemented in the 32-33 GHz band. The sharing between FS/ISS, including GSO-GSO, non-GSO-non-GSO, as well as GSO-non-GSO-links, is analysed with respect to the interference to point-to-point systems. However, the studies indicate that the results are applicable to P-MP systems.

b) HDFS/radionavigation service (RNS)

The sharing studies have, in accordance with Resolution **126 (WRC-97)**, been conducted in order to determine the necessary criteria in order to ensure the sharing between the FS and the RNS.

The term "radionavigation" throughout the text is referring to an airborne radar system operating in the 31.8-33.4 GHz band. One administration has reported worldwide use of this band for the radionavigation service in terms of a limited number of airborne radar systems. These radar systems are aboard aircraft used to provide humanitarian assistance to administrations worldwide in time of national emergency or natural disaster. The actual radar system is used for ground-mapping, weather avoidance and navigation, as well as airport approach and landing where land-based radars for that purpose may be unavailable or insufficient. Radar operations at millimetre wavelengths provide greater positioning and identification accuracy for navigational updates than at lower frequencies, and can provide the aircrew with visual quality radar images even under conditions of inclement weather or other airfield obscuration. Two radar systems are implemented: one system using fixed frequency (25-30 aircraft) and one system (50 aircraft) using frequency agility (selected pairs out of nine channels across the band 32.2-33 GHz). The sharing studies assumed that the mobile radar systems operate worldwide with a required protection ratio of I/N = -6 dB not to be exceeded for more than 0.1% of the operational flight time.

In the conducted sharing studies (radionavigation into HDFS), calculation of separation distance is based on a probabilistic approach as well as on a deterministic approach (worst case). The studies show that if the required minimum separation distance between systems in the two services to preclude interference cannot be assured, then appropriate mitigation techniques, including frequency coordination, and/or restrictions may be needed to facilitate frequency band sharing. Operational restrictions, if applied to airborne radars in the radionavigation service, may have some impact on the performance of these radars, and should be further studied.

The studies indicate that the concept of geographical coordination may be difficult to apply for the mobile radar system.

Required criteria, in terms of required separation distances (between HDFS and radionavigation), mitigation techniques and operational conditions, are determined in the conducted sharing studies. Propagation models used include Recommendations ITU-R P.452-8 and ITU-R P.676-3. The antenna radiation patterns are modelled by Recommendations ITU-R F.699-4, ITU-R F.1245 and ITU-R F.1336.

The studies have shown that below certain altitudes and down-tilt angles of its antenna, airborne radars operating in the RNS may cause interference to HDFS. It is possible that these particular modes of the radar represent a small per cent of time of its overall operation, or that operational agreements between the services can be reached on a local basis to minimize the amount of time that these modes are used. In either of these cases, the potential for interference can be greatly minimized. Furthermore, it has been identified that the frequency of radionavigation systems are either selectable or use discrete channel frequencies. The frequency agility of these radars could be a mitigation technique to reduce the interference, but further studies are needed. It appears that altitude restriction and antenna down-tilt limitation may not be able to be met by the radionavigation systems.

Both of the above possibilities will require further examination and cooperation between the radio services in the future.

Technical characteristics for the considered P-P and P-MP systems in the FS are based on inputs from Recommendation ITU-R F.758-1 (MOD) [Doc. 9/1022].

6.1.1.2 Analysis of the results of studies

For the applications described above the frequency band 31.8-33.4 GHz is suitable to satisfy the HDFS characteristics, including the availability and performance requirements.

6.1.1.2.1 Sharing between HDFS and space research service (SRS)

Sharing between the FS and the SRS in the 31.8-32.3 GHz portion of the band was analysed with respect to P-P systems, noting that there are currently no more than four large earth stations in the world to consider. So far, there is only one station (Goldstone, California) in operation and two stations (Canberra, Australia and Madrid, Spain) are planned for operation by 2002. Additionally, one station is planned (Perth, Australia), and future use is indicated for roughly ten additional stations.

Concerning protection criteria to the SRS earth stations in the 31.8-32.3 GHz band, Recommendation ITU-R SA.1157 is applicable. This corresponds to an interference level of -216 dB(W/Hz) not to be exceeded for more than 0.001% of time.

Studies of co-frequency sharing between typical HDFS and SRS systems (deep space, space-to-Earth) in the 31.8-32.3 GHz band have been conducted. Worst-case coordination distances between a receiving earth station and an urban area (18 million people with a fully-implemented network of three simultaneously-transmitting point-to-point links per square kilometre) would be in the 216 km to 259 km range. The distance depends on the particular HDFS system considered, however, a number of factors would tend to significantly reduce those distances. These include both natural and intentional shielding, distribution of the HDFS transmitters throughout the urban area, and the probability that one or more HDFS transmitters are pointing towards the earth station.

Taking these factors into account, the required separation distance is expected to be significantly less than the coordination distances. These separation distances indicate that the sharing of spectrum is feasible between the two services.

In the frequency band 31.8-32.3 GHz, the expected interference levels from transmitting space research space stations (deep-space) into receiving HDFS stations is considered to be acceptable at the current operating emission levels from the space research systems when in deep space. It would be appropriate to adopt a suitable free-space spectral pfd limit at the surface of the Earth in order to provide adequate protection to HDFS systems from SRS satellites in a temporary near-Earth orbit phase. Since only limited studies based on a few specific systems have been performed, it may be appropriate to adopt pfd limits found to be suitable for protecting the HDFS in neighbouring bands, such as 37-38 GHz.

The 31.3-31.8 GHz band is extensively used by the radio astronomy service for continuum observations at many locations worldwide as well as from space. It is also used by the EESS (passive) for meteorological observations. In implementing HDFS systems in the 31.8-32.3 GHz band, account should be taken to adequately protect those sensitive services. The harmful interference threshold levels for the RAS and EESS (passive) are listed in Recommendations ITU-R RA.769 and SA.1029, respectively.

6.1.1.2.2 Sharing between HDFS and inter-satellite service

No ISS systems have so far been implemented in the 32-33 GHz band. However, by applying a realistic pfd mask (-135/-115 dB(W/(m^2•MHz)) (see § 6.1.1.3.3) and typical ISS-link configurations, simulations show that the FS long-term and short-term criteria are met.

6.1.1.2.3 Sharing between HDFS and radionavigation service (RNS)

a) RNS into HDFS

The pulsed nature of the interfering radar signal allows for shorter separation distances compared to a non-pulsed interfering source. This has been taken into account in the relevant sharing studies as well as the impact of short duration pulsed, extremely high-power interference of the airborne radar system into the HDFS-receiver.

The studies indicate that severe interference events may occur during exceptional main beam coupling between the antennas of the radar system and the fixed system.

Various combinations of aircraft altitudes, radar tilt angle and fixed system antenna elevation angle can generate such events. However, the probability of occurrence of such events is expected to be low. Furthermore, the events will be short in duration due to the narrow radar antenna beam and the antenna rotation. Further studies are required in order to assess the overall effects of high power radar interference into HDFS receivers.

The studies outline necessary criteria, in terms of required mitigation techniques (see § 6.1.1.1.2b) for the HDFS and limitations on radar operational altitude and/or tilt angle in particular over urban areas. The studies indicate that the HDFS elevation angle and the radar tilt angle are crucial.

In cases where suitable mitigation techniques for the HDFS and/or restrictions on operational conditions for the RNS are not applicable, appropriate and agreed operational procedures should be applied.

b) HDFS into RNS

Since the airborne radar is operated throughout all phases of aircraft flight, it is not apparent that interference, without countermeasures, can be avoided in all cases.

Conducted sharing studies considering P-P systems show that required unavailability criterion (0.1%) of the airborne radar system will be met, assuming worst-case scenarios and operational altitudes above approximately 4 000 metres and limitations on the tilt angle.

Considering high-density P-MP applications, assuming densities of 1 000 terminal stations/km^2 and 0.3 central stations/km^2, respectively, the sharing studies, using practical assumptions, show that the performance of the airborne radionavigation radar will be acceptable over urban areas. This conclusion assumes that the aircraft operates at altitudes above 6 000 metres and with antenna down tilt angles between -20 to -30°. In addition, the antenna elevation angles of HDFS stations, oriented toward the aircraft, must not exceed approximately 5°.

HDFS systems may occasionally require higher elevation angles than 5° in dense urban areas. For these cases appropriate mitigation techniques should be taken into account in order to reduce the interference to the airborne radar system.

Mitigation techniques such as shielding effects, improved antennas, Automatic Transmitter Power Control (ATPC), etc. implemented in future P-MP applications may ensure that the availability criteria of the airborne radar system will be met. Concerning mitigation techniques for the radar system, further information is required regarding interference mitigation techniques that are in use or planned to be used in future radionavigation equipment in the 31.8-33.4 GHz band.

6.1.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

In order to satisfy the agenda item, the FS systems in this band should be accommodated for HDFS usage, recognising the needs of other services already allocated to these bands.

6.1.1.3.1 Sharing between HDFS and SRS

Sharing between the SRS and the FS is feasible in the band 31.8-32.3 GHz if a suitable free-space spectral pfd limit at the surface of the Earth is adopted for the space research service. An appropriate pfd limit could be determined by applying the following method:

Adopt a provisional pfd limit as established for non-GSO SRS satellites in the band 37-38 GHz and conduct, if necessary, further studies in order to allow for precise determination of a suitable pfd limit to protect HDFS while not unduly constraining the SRS.

6.1.1.3.2 Sharing between HDFS and RNS

The sharing studies show that the band 31.8-33.4 GHz could be used by the FS and the RNS if certain technical and operational measures are taken by both services.

Enhancements to future FS systems in terms of robust Forward Error Correcting (FEC) coding are easy and relatively inexpensive to implement. In particular, in combination with bit interleaving (draft revision of Recommendation ITU-R F.1097 (MOD) (Doc. 9/1020)), FEC has shown to be efficient with respect to burst errors. In order to further improve the sharing possibilities, certain access/modulation techniques less susceptible to pulsed energy and robust synchronization schemes are available to the FS. In addition, improved antennas combined with modest limitations on elevation angle will increase the protection of both systems. However, too stringent limitations on antenna elevation angle may tend to limit the architecture of P-P and P-MP systems to be deployed in the 31.8-33.4 GHz band.

Concerning the airborne radar system, possible measures include consideration of operational altitude and antenna down-tilt angle, priority channel schemes and pulse coding.

Mitigation techniques in terms of pulse coding for the RNS mean that the radar transmits a coded sequence in each burst (a "signature" for the radar station equivalent to the principle of spread spectrum systems). The processing gain achieved thereby has the effect of increasing the signal-to-noise ratio in the radar receiver, which improves the radar performance in an interference environment.

Similar RNS applications in other bands have implemented pulse coding as an efficient mitigation technique.

Retrofitting existing radionavigation equipment with pulse coding circuitry would not be feasible but the requirement for future equipment is possible.

However, in order to provide some measures of protection for the FS, in particular in urban areas, the RNS may be able to take certain operational measures, such as channel selection, to reduce interference and limitations on operational altitude and/or tilt angle. The specifics and effects of these restrictions should be further studied in ITU-R.

In particular, the frequency agile mode of the RNS system will improve the sharing possibilities. This should be viewed in the light that operational limitations on the RNS may in some cases be difficult to implement due to the high mobility of the service and the demands of the service to use the full capability of the system when sufficiently removed from the urban environment.

Band segmentation would reduce the efficiency of spectrum use providing less bandwidth needed for the frequency hopping systems in the RNS and possibly insufficient bandwidth for channel plans and separation requirements for forward and return links in the FS. Consequently, band segmentation has the disadvantage of less efficient use of the resource in terms of available spectrum and thus should not, if possible, be implemented.

6.1.1.3.3 Sharing between HDFS and ISS

The studies show that the 31.8-33.4 GHz band could also be shared by the FS and ISS (no ISS system implemented so far in the 32-33 GHz ISS band). In the absence of any actual data, a LEO SAT 1 type constellation has been simulated with 288 satellites, each communicating to its four nearest neighbours.

The system uses power control to achieve a C/N of 25 dB on each link. The ISS beam is assumed to conform to Recommendation ITU-R S.672-3, with a 3 dB beamwidth of 0.7º and a peak gain of 48 dBi.

Used short-term and long-term criteria for the FS are +1.5 dB and -13.5 dB not to be exceeded for more than 0.1% and 20% of time, respectively.

The conducted sharing studies indicate, so far, that FS will be protected by the following pfd mask for future non-GSO ISS system:

-135	dB(W/(m^2•MHz) for $0° \leq \delta < 5°$
-135 + (δ-5)	dB(W/(m^2•MHz) for $5° \leq \delta < 25°$
-115	dB(W/(m^2•MHz) for $25° \leq \delta < 90°$

where δ is the angle of arrival (degrees).

6.1.1.3.4 Summary

The studies show that the 31.8-33.4 GHz band could be used by high-density systems in the fixed service and the other services in the band, with some limitations on all services. This conclusion should be viewed in the light that the 31.8-33.4 GHz band, with high potential for wideband HDFS applications, is not shared with FSS. Bearing in mind the increasing sharing problems between HD applications for FS and FSS in shared bands, this potential should be utilized.

In addition, the band is sparsely implemented by the other services. RNS, operated worldwide, is implemented by one administration; ISS is not implemented so far.

6.1.1.4 Regulatory and procedural considerations

Concerning the sharing between the FS and the RNS in the 31.8-33.4 GHz band, appropriate ITU-R Recommendations could be developed rather than modify the RR.

Concerning the sharing between the FS and the ISS in the 32-33 GHz band, Article **S21** may need to be revised by the WRC, taking into account the proposed pfd mask described in § 6.1.1.3.3.

Concerning the sharing between the FS and the SRS in the 31.8-32.3 GHz band, it may be appropriate to adopt the same pfd limit for SRS in Article **S21** as proposed for the non-GSO SRS in the band 37-38 GHz band. Taking into account the proposed methods to satisfy agenda item 1.4, it may be appropriate to suppress Resolution **126 (WRC-97)** and to delete No. **S5.547A**.

6.1.2 Resolution 133 (WRC-97) "Sharing between the fixed service and other services in the band 37-40 GHz"

6.1.2.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

There is a strong interest worldwide from both the fixed-satellite service (FSS) and the fixed service (FS) communities for access to spectrum in the 37.5-42.5 GHz range. Sharing between the two services has been shown to be technically feasible, particularly where the FS and/or the FSS would not rely on the ubiquitous deployment of terminals.

The appropriate power flux density limits to protect the FS from the FSS strongly depend on the technical parameters of both the FS and FSS and the type of deployment of the FS stations. At the same time, the FSS may be limited in its ability to reduce power flux densities to the levels intended to protect the FS. Adopting power flux-density limits on FSS satellites in the band 37.5-40.0 GHz that are adequate to protect all applications in the FS would constrain non-GSO and GSO FSS systems, and constrain their ability to serve earth terminals with small receive antennas. Conversely, adopting power flux-density limits that would enable FSS systems to serve earth terminals with small receive antennas would constrain the performance of some applications in the FS. However, pfd limits could also be developed, which would provide an equitable balance of constraints on both services.

Point-to-point FS systems are already deployed on a large scale and their use is growing in the 37-40 GHz range which is allocated to the FS on a primary basis. The initial large-scale deployment of P-P systems in this band was in mobile and competitive market networks with a concentration mainly in and around urban and industrial areas. A more recent large-scale FS application of this band represents a new variety of FWA using P-P and P-MP systems that terminate directly on subscriber premises. While the current major use of the 38 GHz band is the application of P-P systems with smaller capacities, there is an accelerating trend toward higher capacities up to *n* x 155 Mbit/s, using higher level modulation methods (e.g. 256-QAM). Deployment levels and further details can be found in draft new Recommendation ITU-R F.[Doc. 9/1015].

In a study addressing the band 37.5-40.5 GHz, the coordination distances between HDFS system transmitters and FSS earth station receivers is relatively small, in the 20 km to 44 km range in the case of point-to-point FS systems, and from 3 km to 15 km in the case of point-to-multipoint systems. Separation distances should be shorter than the reported coordination distances. Because of the expected HDFS systems in areas of high population or concentrated commercial activity (i.e. urban areas), and possibly a similarly high density of receiving FSS earth stations in parts of the same areas, the required separation distances between the two system types would make co-frequency operation of one or the other type of system difficult within all or some of an affected area. However, mitigation techniques could facilitate sharing. This matter requires further study. It should be noted, however, that because of the short separation distances involved, administrations may wish to make the spectrum management decision of whether to use one or the other or both of these types of systems on a national basis. Because of the short separation distances involved, international coordination is not expected to be difficult, except perhaps in border regions.

The band 37-38 GHz is allocated to the FS, MS, SRS and FSS (37.5-38 GHz) on a co-primary basis. The SRS and FSS allocations are in the space-to-Earth direction.

Preliminary studies to determine the coordination area of SRS and FSS earth stations in the band 37.5-38 GHz have not yet been carried out.

A number of preliminary studies have been carried out by various administrations for sharing between HDFS and FSS. These studies were based on aggregating the emissions of many HDFS transmitting stations over a large population centre into a single equivalent transmitting station. This simplifying method further assumes that the propagation conditions from stations dispersed over an area to a distant earth station are comparable to the conditions from a single equivalent point to the earth station. Further study is required by ITU-R to validate the above assumptions and to provide guidance on how to account for anomalous propagation conditions for small percentages of time between a population of HDFS transmitting stations and a distant earth station.

The following Recommendations have been considered in the studies: ITU-R IS.847, SA.1157, F.758, SA.1344, draft new Recommendations SA.[Doc. 7/18(Rev.1)] and F.[Doc. 9/1015], SA.609, SA.1015, M.1316, P.452 and P.620.

6.1.2.2 Analysis of the results of studies

6.1.2.2.1 Sharing between FS and FSS

Coordination of FSS earth stations with FS stations is the most critical sharing aspect in the frequency band 37-40 GHz to be considered under item 2 of Resolution **133 (WRC-97)**. This is due to such factors as propagation conditions and the rapidly progressing HDFS deployment in urban, suburban and industrial areas.

In general, coordination between FS stations and FSS earth stations can be exemplified by the following scenarios:

– Areas without FS deployment

  The geographical areas in which the FSS will not need to coordinate with the fixed service will be larger in the 37-40 GHz band in comparison with the currently shared lower frequency bands (e.g. below 30 GHz) where the fixed service deployment is spread out over much larger geographical areas.

– Areas with sparse FS deployment

  In intermediate cases, where the fixed service is sparsely deployed, station-to-station coordination is feasible.

– Areas with dense FS deployment

  In service deployment areas where there is dense deployment of fixed service stations, coordination with and by FSS earth stations should be carried out on a basis other than a station-to-station basis. CPM-97 reported in § 7.5.3.2, paragraph 1, that because HDFS intra-service station distances are substantially smaller than inter-service separation distances, coordination with and by other services should be carried out for HDFS service areas instead of individual HDFS stations.

The feasibility of coexistence between the FS and FSS within the same deployment areas depends on:

i) the actual parameters of both systems;

ii) minimum operational elevation angles of the non-GSO systems;

iii) off-axis antenna gain of both systems;

iv) the terrain topography;

v) type of FS system (P-P or P-MP); and,

vi) FS and/or FSS deployment density.

The results of studies conducted in the ITU-R of known and proposed non-GSO FSS systems, and of known and proposed P-P and P-MP FS systems, indicate that maximum allowable values of power flux-density of -120/-105 dB(W/(m^2·MHz)) at the surface of the Earth would be adequate to protect terrestrial services from non-GSO FSS networks in the frequency band 37.5-40.5 GHz. Studies supporting this conclusion are summarized in Annex 1 of draft new Recommendation ITU-R SF.[Doc. 4-9/1008]. The studies were based on the point-to-multipoint and point-to-point FS system characteristics considered at the time to be the most representative. Systems with higher elevation angles and lower fade margins could be more sensitive.

Previous studies within the ITU-R had not allowed conclusions to be drawn as to the adequacy of the current power flux-density limits for the band 37.5-40 GHz to protect terrestrial services from GSO FSS satellites. For a single GSO satellite operating at the current Article **S21** power flux-density limits, the in-line interference level (I/N) at an FS receiver with a 44 dBi antenna is -4.4 dB when the FS receiver is at a 0° elevation angle, and 11 dB when the FS receiver is at a 10° elevation angle. In order to meet the long-term interference criterion, I/N = -10 dB, the separation angle between the FS receiver and the GSO arc should be no less than 1.7°. In any FS system deployment, a small percentage of links may point at the GSO arc. For those point-to-point FS systems that do not implement any orbital avoidance, the FS receiver could experience interference above the long-term interference criterion when the separation angle from the GSO arc is less than 1.7°. Arc avoidance is not generally applied to most FS applications in this band, but this and other potential mitigation approaches have not been fully studied.

Some administrations have concluded that current ITU-R power flux-density limits of -115/-105 dB(W/(m^2·MHz)), as currently specified in Article **S21** for FSS systems in the band 37.5-40.5 GHz, are adequate to protect the FS from GSO FSS networks in the band 37.5-40.5 GHz.

On the basis of studies carried out by one administration, some administrations had concluded that in the case of interference from a fully populated arc of GSO satellites, the aggregate interference into the FS receiver at 10° elevation angle exceeds the long-term interference criterion for a large range of azimuths. Furthermore, these administrations had also concluded that in the band 37.5-40.5 GHz, for an FS receiver at 10° elevation, a power flux-density level of -140/-105 dB(W/(m^2•MHz)) would ensure that the long-term criterion would be met for all azimuths. In this case it was concluded that this could preclude operation of GSO FSS systems.

Further details can be found in draft new Recommendations ITU-R F.[Doc. 9/1015] and SF.[4-9/1008] (submitted to RA-2000).

On the subject of power flux-density limits for GSO FSS satellites to protect fixed service systems in the 37.5-40 GHz band, some administrations provided results of recent studies directly to CPM-99-2. Based on these studies, some administrations proposed the following power flux density mask (see Table 6-1), as a compromise intended to adequately protect the fixed service without unduly constraining the FSS in this band:

TABLE 6-1

pfd limits for GSO FSS in the band 37.5-40 GHz

Power flux-density limit in dB(W/(m^2•MHz))	Angle of arrival δ above the horizontal plane
-125	$0° \le \delta < 5°$
-125 + (δ - 5)	$5° \le \delta < 25°$
-105	$25° \le \delta$

6.1.2.2.2 Sharing between FS and SRS

Studies conducted in ITU-R have indicated the following sharing possibilities between space research systems and HDFS systems. The findings are summarized as follows:

a) Sharing of spectrum in the 37-38 GHz band is feasible between HDFS systems and deep-space space-to-Earth links such as the planned Mars-to-Earth links. Interference levels into HDFS receivers are 25 to 30 dB below thermal noise levels. Coordination distances between a receiving earth station and a full-implemented HDFS system in a large urban area may be up to 260 km, but actual required separation distances between the earth station and the urban area are expected to be significantly less than the coordination distance.

b) Sharing between HDFS systems and Moon-to-Earth space-research systems is feasible with some constraints. Coordination distances between an earth station of Moon-to-Earth links are typically in the 120 km range, but again the actual required separation distances are expected to be significantly smaller that that limit. Transient interference levels at HDFS receivers from Moon transmissions have a pfd around -129 dB(W/(m^2•MHz)). This pfd level is considered to be close to the interference limit of HDFS receivers, but mitigation measures such as higher G/T and a lower e.i.r.p. in the Moon-to-Earth link and a designed-for higher I/N ratio in HDFS links operating at high elevation angles are available to permit sharing to take place.

   Statistical analysis for conjunction of the Moon within the 10 dB beamwidth of an HDFS receiver antenna has shown that the probability is dependent on the gain of the antenna and the pointing direction. Simulations have shown that the probability of conjunction is between 0.0033% for a 47 dBi gain antenna and 0.097% for a 40 dBi gain antenna. The average duration ranges between five minutes and ten minutes depending on the gain of the HDFS receiver.

c) Sharing between HDFS systems and space-to-Earth space very-long-baseline interferometers (S-VLBI) has similar characteristics as that between HDFS systems and Moon-to-Earth links. Transient interference levels at HDFS receivers are marginal, but easier mitigated against in the S-VLBI case because the interference duration is only about eight seconds. Peak interference levels are not greater than 7 dB below the HDFS thermal noise level. Coordination distances between a full complement of HDFS transmitters in a large urban area and an earth-station receiver is about 67 km to protect wideband data, but up to 265 km to protect narrow-band (2-3 MHz) timing signals.

6.1.2.2.3 Impact of the FS-FSS sharing scenario on SRS

In consideration of Resolution **133 (WRC-97)** pfd limits either included in Article **S21** or derived for the FSS to protect FS systems may not adequately protect the SRS systems. Preliminary results of studies of sharing between the SRS and the FSS in the bands 37.5-38 GHz and 40-40.5 GHz indicate that sharing may be feasible for certain types of FSS systems. These studies further show that power flux-density limits more stringent than the current limits of –115/-105 dB(W/(m^2•MHz)), and the acceptance of certain operational constraints by the SRS, may be needed to facilitate satisfactory SRS and FSS operations in the 37.5-38 GHz band.

6.1.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

In order to satisfy the agenda item the FS systems in this band should be accommodated for HDFS usage.

6.1.2.3.1 Space research service

The technical and operational studies that have been carried out have concluded that sharing between the fixed and the space research services in the 37-38 GHz band is feasible.

Some operational constraints on the SRS are necessary to facilitate sharing, depending on the type of space mission (i.e. deep space or Moon-to-Earth) and the density and geographical location of terrestrial FS systems.

Although some space research systems are operating with a pfd of -129 dB(W/(m^2•MHz)), there is a concern that future SRS satellite systems may be implemented with higher power-flux densities on the surface of the Earth. Article **S21** permits pfd of -115 dB(W/(m^2•MHz) at low angles of elevation, and -105 dB(W/(m^2•MHz) at high angles of elevation, under free-space propagation conditions. These regulations were drafted several years ago, however, primarily for the sharing of more conventional fixed systems with satellite systems in the GSO orbit. With current technology of many satellite systems in non-GSO orbits and HDFS fixed systems operating at high elevation angles, lower power-flux density levels are required in the band 37-38 GHz.

In addition, the requirements of the radio link used to synchronize the operation of space-very-long baseline interferometry (S-VLBI) need to be considered. A narrow band (i.e. 2-3 MHz) to protect the very high C/N requirement of the timing circuit could be identified in the 37-38 GHz band. This 2-3 MHz could be at the lower band edge so that the deployment of HDFS is not unduly restricted.

A free-space power flux-density limit at the surface of the Earth in Table **S21-4** revised for FSS under Resolution **133 (WRC-97)** has an impact on protection of some SRS earth stations. The FSS power flux-density limit may not be adequate to protect some SRS earth stations. Mitigation techniques and other technical methods to facilitate coordination between the SRS and the FSS in the band 37.5-38 GHz continue to be studied and, if required, the results shall be brought to the attention of a competent conference.

On the basis of studies conducted in the ITU-R of known and proposed non-GSO FSS and FS systems, it is concluded that the same power flux-density limits of -120/-105 dB(W/(m^2•MHz)) in the band 37.5-40.5 GHz may be adequate to protect terrestrial services from emissions of non-GSO SRS satellites in the band 37-38 GHz. A similar approach may be considered for GSO SRS satellites, that is to use the GSO FSS pfd limit, as long as the low pfd limit is not significantly less than the value agreed for the non-GSO SRS.

Appropriate pfd limits could be determined by applying the following methods:

For non-GSO SRS satellites, WRC-2000 could adopt the pfd limits proposed for non-GSO FSS satellites in the band 37.5-38 GHz, i.e. -120/-105 dB(W/(m^2•MHz)).

For GSO SRS satellites, WRC-2000 could adopt the limits proposed for GSO FSS satellites, as long as the lower pfd limit is not significantly less than -120 dB(W/(m^2•MHz)). The currently identified lower value of -125 dB(W/(m^2•MHz)) may be acceptable to the SRS.

Conduct, if necessary, further studies in order to allow for precise determination of a suitable pfd limit to protect HDFS networks from a relatively small number of SRS satellites without unduly constraining the SRS.

6.1.2.3.2 Fixed-satellite service

The ITU-R concluded, on the basis of studies of certain known and proposed non-GSO FSS and FS systems, that power flux-density limits of -120/-105 dB(W/(m^2•MHz)) in the band 37.5-40.5 GHz would be adequate to protect terrestrial services from non-GSO FSS networks.

Two methods to satisfy the agenda item were identified:

Method A

Method A is to adopt the agreed power flux-density limits in draft new Recommendation ITU-R SF.[Doc. 4-9/1008] for non-GSO FSS (as mentioned above), and is to adopt the following pfd limits (see Table 6-2) developed at CPM99-2 for GSO FSS in the band 37.5-40 GHz:

TABLE 6-2

pfd limits for GSO FSS in the band 37.5-40 GHz

Power flux-density limit in $dB(W/(m^2 \cdot MHz))$	Angle of arrival δ above the horizontal plane
-125	$0° \leq \delta < 5°$
$-125 + (\delta - 5)$	$5° \leq \delta < 25°$
-105	$25° \leq \delta$

Advantages

- The tightening of the existing pfd limits will facilitate the deployment of high density applications in the fixed service.
- These pfd limits allow access to the band for both services without undue constraints on either service, and provides the consequential benefit of more efficient use of spectrum.
- No further studies are required and a decision could be made at WRC-2000.

Disadvantage

- Some GSO FSS applications may not be able to implement certain services to small antenna earth station terminals.

Method B

Since the sharing issues between the FS and the FSS in the 37.5-40 GHz range have not been fully resolved, solutions could take the form of power flux-density limits that vary among band segments. Method B would build upon the conclusions reached with regard to non-GSO FSS power flux-density limits, and support the development of a comprehensive sharing approach for the 37.5-42.5 GHz band that includes provision for FS systems and both non-GSO FSS and GSO FSS systems. This method connects the 37.5-40 GHz band with the 40.5-42.5 GHz band (see § 6.1.5.2) and envisions a solution that would encompass the entire 37.5-42.5 GHz range. Under this approach, the conclusions reached with regard to non-GSO FSS power flux-density limits are not sufficient to resolve in full the sharing situation between the FSS and the FS in this band.

Advantages

- The result of such different limits would encourage the development of ubiquitous, high-density FS and FSS applications in different portions of the band, and would require only minor modifications to the existing FSS allocations to obtain global co-primary FS and FSS allocations in the 37.5-42.5 GHz band.

- Depending on frequency bands and pfd limits proposed under this method, a decision on the pfd limits in particular frequency bands may be taken at WRC-2000.
- Provides a global sharing approach that is equitable and allows for future growth of both services.

Disadvantage

- May have some impact on the fixed service in administrations that have made FS assignments in this frequency range.

6.1.2.4 Regulatory and procedural considerations

6.1.2.4.1 Space research service

Any sharing solution would be based on the concept of coordination. In terms of administration for Member States and the ITU-R there may be a small extra overhead required in maintaining a database of the location of SRS earth stations in various regions of the world.

Any change to the frequency allocation would require changes to Article **S5** and any changes to pfd limits would need to be reflected in changes to Article **S21**. Also any changes in coordination may need to be reflected in Appendix S7.

A narrow band of 2-3 MHz could be identified to satisfy the S-VLBI timing requirements for synchronization operation in the 37-38 GHz space-to-Earth band. The location of this band could be at the lower end of the 37-38 GHz band in order to facilitate coordination with FS stations.

6.1.2.4.2 Fixed-satellite service

Regulatory and procedural means to resolve the sharing situation between FS and FSS terminals in the 37.5-40 GHz range may take a number of forms, including possible modifications to Table **S21-4** and associated notes.

6.1.3 Resolution 726 (WRC-97) "Frequency bands above 30 GHz available for high-density applications in the fixed service"

The frequency bands 31.8-33.4 GHz, 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz relate to this Resolution.

General information on the high-density applications in the fixed service (HDFS) above 30 GHz and on sharing between HDFS and other services in the frequency band 31.8-33.4 GHz are contained in § 6.1.1.

6.1.3.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

WRC-97 reviewed the frequency allocations in the range 50-70 GHz based on comprehensive technical studies (as detailed in the CPM-97 Report) in order to protect EESS (passive) systems within this frequency range.

The band 51.4-52.6 GHz is allocated to the fixed and mobile services on a primary basis with the radio astronomy service allocated by No. **S5.556**. Furthermore, the RAS shares the band 58.2-59 GHz with the FS, the MS, the EESS (passive) and the SRS (passive) and the band 64-65 GHz with the FS, the MS and the ISS by No. **S5.556**. In addition, the band 55.78-59 GHz is shared on a primary basis among the FS, MS, ISS, EESS (passive) and SRS (passive), while the FS, MS, ISS, EESS and SRS share the band 65-66 GHz on a primary basis. No. **S5.547** provides for the introduction of high-density FS applications into these bands.

ITU-R has developed the following relevant Recommendations:

ITU-R SA.1259, SA.515, SA.1029, RA.769, F.758 and draft new Recommendations ITU-R F.[Doc. 9/1013] and F.[Doc. 9/1014] (submitted to RA-2000).

Potentially, these bands could accommodate the application of P-P and/or P-MP HDFS systems. System characteristics for HDFS systems using the frequency band 51.4-52.6 GHz are available in Recommendation ITU-R F.758 for P-P and P-MP systems, for the frequency bands 55.78-59 GHz and 64-66 GHz only for P-P systems. For P-MP systems in the bands around 60 GHz no system characteristics have been developed. Provisionally the defined system characteristics of P-MP systems in the band 51.4-52.6 GHz can be used for sharing studies.

Rain outage events are the primary cause of unavailability. In the band 55.78-59 GHz the possible hop length for point-to-point hops will be reduced furthermore by high O_2 absorption losses. Applications typically have to meet availability demands of 99.99% to 99.999% per year. Hop lengths to range from about 7 km down to about less than 1 km for point-to-point systems are possible in the considered frequency bands, depending on frequency, availability criteria, rain zone and transmission capacity.

For point-to-multipoint systems, hop lengths up to about 1 km are achievable at 51.4-52.6 GHz. This would give reasonable coverage ranges for access systems in dense urban areas. High propagation and precipitation losses in the bands around 60 GHz and the low antenna gain at the central station of a P-MP system might restrict the use of such systems. Nevertheless taking into account inter- and intra-system interference, there are also opportunities for these bands for the use in dense urban areas.

6.1.3.2 Analysis of the results of studies

For the applications described above the frequency bands 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz are suitable to satisfy the system characteristics, including the availability and performance requirements. Results of sharing studies for the bands mentioned in Resolution **726(WRC-97)** are described below (see § 6.1.1 of the CPM Report for the band 31.8-33.4 GHz).

6.1.3.2.1 Radio astronomy service

The RAS shares the 51.4-52.6 GHz, the 58.2-59 GHz and the 64-65 GHz bands with other services by national arrangement. There is currently no known usage of these bands by the radio astronomy service community (potentially due to atmospheric absorption) and no studies on potential sharing have been done to date. Even if some radio astronomical use developed, there should not be any problems with radio astronomy stations sharing this band with HDFS since use of these bands by the radio astronomy service must already be coordinated with the FS within individual administrations. Therefore, sharing between HDFS and RAS is a domestic issue.

6.1.3.2.2 Space research service (passive)

The SRS (passive) is covered under Recommendation ITU-R SA.1259. There is currently no plan for the space research service allocations within the 55.78-59 GHz or the 65-66 GHz bands.

6.1.3.2.3 Earth exploration-satellite service (passive)

Even though the EESS does not use the 51.4-52.6 GHz band, it does rely on the 50.2-50.4 GHz band for critical atmospheric measurements. These measurements are very sensitive to interference.

Therefore to avoid exceeding the protection criteria of EESS within the 50.2-50.4 GHz band, as provided within Recommendation ITU-R SA.1029-1, high-density FS applications must adhere to the spurious emission limits shown in Tables I and II of Appendix **S3**.

Pre-WRC-97 studies showed that, based on technical parameters for the FS given in Recommendation ITU-R SA.1259, the sharing between the FS and EESS is feasible in the 55.78-59 GHz band. The technical parameters assumed for the studies are worst-case values for the FS, and the currently known parameters of planned FS systems in the band 55.78-57 GHz are not significantly different from those assumed in Recommendation ITU-R SA.1259. Additional studies are ongoing within ITU-R for the sub-band 55.78-56.26 GHz.

However, if new FS systems use different technical parameters or deployment scenario from those assumed in Recommendation ITU-R SA.1259, further studies might be needed to determine the impact on the interference to EESS, using a different methodology if needed.

In order to minimize the possibilities of unacceptable interference to passive sensor in the band 55.78-56.26 GHz, and since the results of sharing studies between the FS and EESS were the most sensitive to the variation of FS parameters in this sub-band, FS parameters could be limited in this sub-band to those which are consistent with Recommendation ITU-R SA.1259. Such a limitation could be included in a footnote and would avoid further studies.

However, these limits might not be necessary as the current parameters of planned FS systems in the band 55.78-57 GHz are not significantly different from those assumed prior to WRC-97.

There is currently no planned usage for the EESS allocation within the 65-66 GHz band and no studies on potential sharing have been done to date.

6.1.3.3 Methods to satisfy the agenda item and their advantages and disadvantages

In order to satisfy the agenda item the FS systems in these bands should be accommodated for HDFS usage.

The following methods can be considered:

Method 1

WRC-2000 could choose to impose some limitations to the FS parameters in the band 55.78-56.26 GHz consistent with the assumptions made in Recommendation ITU-R SA.1259. Such limitations could be one of the following:

a) The insertion of the footnote "In the band 55.78-56.26 GHz, the output power density of stations in the FS shall be limited to -21.5 dB(W/MHz), and the far side-lobe antenna gain above 40° from the main beam shall comply with the following mask:

- for $40° < \theta < 65°$ G = -(3/25) x θ -11/5 (dBi)
- for $\theta > 65°$ G = -10 dBi

where θ is the off-axis angle."

b) The insertion of the footnote "In the band 55.78-56.26 GHz, the e.i.r.p. density of stations in the FS shall comply with the following mask (in dB(W/MHz)):

- for $\theta < 40°$ no limitation
- for $40° < \theta < 65°$ e.i.r.p. density = -(3/25) x θ - 118.5/5 (dBi)
- for $\theta > 65°$ e.i.r.p. density = -31.5 dBi

where θ is the off-axis angle."

c) The consideration of an output power density limit such as -28.5 dB(W/MHz) in the sub-band 55.78-56.26 GHz.

Further studies could be carried out if new FS parameters exceeding these limitations or using different deployment scenario are envisaged in the sub-band 55.78-56.26 GHz.

Advantages

- HDFS systems can be implemented in the whole 55.78-57 GHz band without undue constraints, while protecting the EESS.

Disadvantages

- Possible uncertainty for the FS if further studies are conducted.

Method 2

WRC-2000 could choose to decide that no further limits are necessary in the band 55.78-56.26 GHz.

Advantages

- HDFS systems could be implemented without additional limitations.

Disadvantages

- If in the future, the FS parameters exceed those assumed in Recommendation ITU-R SA.1259, it could cause the potential loss of data that could lead to serious degradation of the usefulness of a unique frequency band that is important to accurate weather prediction and a permanent limiting of fundamental weather prediction capabilities.

6.1.3.4 Regulatory and procedural considerations

Depending on the solution chosen at WRC-2000 for the band 55.78-59 GHz, either a footnote with text to be decided during the Conference or no action are possible regulatory solutions. Additionally, Resolution **726 (WRC-97)** may have to be modified or deleted as appropriate.

6.1.4 Resolution 128(WRC-97) "Allocation to the fixed-satellite (space-to-Earth) service in the 41.5-42.5 GHz band and protection of the radio astronomy service in the 42.5-43.5 GHz band"

6.1.4.1 Summary of technical and operational studies

6.1.4.1.1 Radio astronomy stations operating in the 42.5-43.5 GHz band

The RAS shares the 42.5-43.5 GHz band on a primary basis with the FS, FSS (Earth-to-space) and MS, except aeronautical mobile service. The band is used for sensitive observations of the extended continuum emission of radio sources. The increasing numbers of RAS stations operating in this band are an indication of the band's importance to the science of radio astronomy. Because of its 1 GHz width and its location in the spectrum (at approximately twice the frequency of the 23.6-24.0 GHz continuum band), it provides an effective point for the sampling of continuum emission at octave or better frequency intervals. A prominent component of the continuum emission observed in the band is due to free-free emission from ionized gas around newly born stars. This band is the optimum frequency to provide critical information on the physical state of the interstellar medium associated with star-forming regions.

The 42.5-43.5 GHz band also contains several molecular spectral lines, e.g. those associated with the silicon monoxide (SiO) molecule which is listed among the radio-frequency lines of greatest importance to radio astronomy in Recommendation ITU-R RA.314-8. SiO transitions have rest frequencies of 42.821, 43.122 and 43.443 GHz. All of these have been detected in interstellar molecular clouds, in the atmospheres of evolved stars, and in external galaxies. The first two lines, observed in the atmospheres of several hundred evolved stars and massive star-forming regions, are extremely important for studies of the birth and death of stars. The SiO maser emission lines are used to determine antenna pointing accuracy for a wide range of radio astronomy observations.

6.1.4.1.2 Relevant ITU-R Recommendations

Studies have resulted in the following Recommendations which deal directly with, or may be relevant to, the protection of radio astronomy stations that may be observing in the 42.5-43.5 GHz band, from out-of-band emissions radiated by space stations in the fixed-satellite service (space-to-Earth) that may operate in the 41.5-42.5 GHz band:

Recommendations ITU-R RA.769-1, RA.517-2, RA.611-2, RA.1237, RA.314-8, SA.509-2 and SM.329-7(Rev.).

6.1.4.2 Analysis of the results of studies

6.1.4.2.1 Protection criteria for the radio astronomy service in the 42.5-43.5 GHz band

Recommendation ITU-R RA.769-1 Tables 1, 2 and 4 list the threshold levels of interference detrimental to radio astronomy observations in the 42.5-43.5 GHz band. The Recommendation assumes 25K antenna and 100K receiver noise temperatures, respectively, an integration time of 2 000 seconds, and a radio astronomy antenna side-lobe gain of 0 dBi toward the source of the interfering signal. All RAS stations operating in this band are used to measure both continuum and spectral line radiation.

The threshold levels of interference in this Recommendation were developed without taking into account the dynamic aspect of a non-GSO constellation. A statistical approach taking account of this dynamic aspect could be achieved via two different approaches:

- The pfd levels of Recommendation ITU-R RA.769-1 not to be exceeded for more than x% of the observing time. A provisional value of x=2 is under study within ITU-R.
- The concept of equivalent power flux-density (EPFD) not to be exceeded for a certain percentage of time. This is similar to that already applied to non-GSO FSS systems in co-frequency situations in lower frequency bands. Interference analysis using this concept should be based on statistical calculations taking into account the characteristics of the RAS stations and the required technical characteristics of non-GSO FSS systems. Further studies are needed to determine the applicability of this approach.

a) Single dish telescopes

Recommendation ITU-R RA.769-1 Table 1, lists the threshold level of detrimental interference for single dish telescopes operating in the 42.5-43.5 GHz band as -227 dB(W/(m^2•Hz)) or -137 dB(W/(m^2•GHz)) for continuum observing, and as -210 dB(W/(m^2•Hz)) or -153 dB(W/(m^2•500 kHz)) for spectral line observations.

b) Very Long Baseline Interferometry (VLBI)

Interferometric arrays with widely separated antennas are less sensitive to interference than single antennas. Telescopes used for VLBI include the U.S. NRAO Very Long Baseline Array (VLBA) stations (Region 2), the antennas used by the European VLBI Network (EVN) (Region 1) and J-NET in Japan (Region 3). Table 4 of Recommendation ITU-R RA.769-1 lists the threshold level of detrimental interference for VLBI stations operating in the 42.5-43.5 GHz band as -173 dB(W/(m^2•Hz)). It should be kept in mind, however, that interference originating from a satellite that is visible simultaneously by two or more VLBI antennas may be received coherently, and if so, this could result in more stringent threshold levels of detrimental interference.

c) Satellites in geostationary orbits

The detrimental threshold levels given in the tables of Recommendation ITU-R RA.769-1 assume that the radio astronomy antenna side-lobe gain towards the interfering source is 0 dBi. As stated in footnote 3 to Table 1 and footnote 2 to Table 2 of Recommendation ITU-R RA.769-1, for transmitters in the GSO orbit, in contrast to those in non-GSO orbit, the detrimental interference levels are 15 dB more stringent. Some administrations feel that the need for this additional 15 dB should be carefully evaluated.

d) Aggregate interference from multiple satellites

The aggregate level of spurious emissions within the RAS band from all FSS satellites above the visible horizon of each RAS station should not exceed the detrimental levels. Several FSS stations in GSO could be within the 10º cone of telescope side-lobe gain >15 dBi for a significant fraction of observing time. Also several satellites from one or more non-GSO constellations could be found within the 38° cone of telescope side-lobe gain >0 dBi for a significant fraction of observing time. Each FSS space station having spurious emissions within the RAS band and at the detrimental levels of Recommendation ITU-R RA.769-1 would exceed the detrimental levels when positioned within these side-lobe cones. Thus each RAS antenna operating in the 42.5-43.5 GHz band would look through an ever-changing grid of emitters which would reduce the area of accessible sky. Further studies are needed to determine the apportionment of the aggregate interference among multiple satellite systems that may be operating in the 41.5-42.5 GHz band.

Many of the proposed non-GSO and GSO FSS systems that plan to operate in the 41.5-42.5 GHz band, may use high gain, narrow beam antennas, with a typical 3 dB beam diameter of less than 250 km. In addition, the propagation impairments are severe in the 41.5-42.5 GHz band. Consequently, proposed FSS systems, operating in this band would operate at high elevation angles, typically 20° or greater. Proposed FSS systems may typically only be able to serve less than 4% of satellite field-of-view at any instant.

e) Suggested elements for future study

As studies progress within ITU-R, the following are among the items that could also be envisaged to ensure protection to the radio astronomy service:

– specifying a maximum pfd level in the band 42.5-43.5 GHz from GSO satellites operating in the band 41.5-42.5 GHz ;
– reducing the implemented allocation with a suitable guardband below 42.5 GHz, with a width to be determined on practical aspects;
– a requirement for coordination between FSS operators and the RAS to limit unwanted emissions in the 42.5-43.5 GHz band at RAS stations which operate in the band; and
– specifying a limit in the band 42.5-43.5 GHz from non-GSO satellites operating the band 41.5-42.5 GHz. This limit could either be a pfd limit not to be exceeded for x% of the time (provisionally 2%), or an EPFD level for a certain percentage of the time.

6.1.4.2.2 Limits for unwanted emissions from space stations

Radio Regulations (RR) Appendix **S3** defines general limits for spurious emissions. Unwanted emissions consist of out-of-band emissions and spurious emissions, where out-of-band emissions extend outward from the centre of the necessary bandwidth B_n to a boundary at $2.5B_n$, while unwanted emissions beyond $2.5B_n$ are classified as spurious emissions. The RR do not set limits on out-of-band emissions. Therefore, wideband FSS systems having necessary bandwidths of order 300 MHz would have an out-of-band boundary separated by 750 MHz from the centre of the necessary bandwidth. Such a FSS system, if operating with a necessary bandwidth edge at the allocated band edge of 42.5 GHz, could have out-of-band emissions extending up to 43.1 GHz, which is 600 MHz within the RAS band, and more than half of its width.

RR Appendix **S3** sets limits on spurious emissions which for space stations is defined in a 4 kHz reference bandwidth and in terms of attenuation (dBc) below the mean power P (in Watts) supplied to the antenna transmission line. Appendix **S3** specifies that for technical or operational reasons more stringent levels than those specified as general limits may be applied to protect specific services, such as safety and passive services, in certain frequency bands.

6.1.4.2.3 Detrimental interference to a RAS station operating in the 42.5-43.5 GHz band from unwanted emissions of FSS (space-to-Earth) space stations operating in the 41.5-42.5 GHz band

An FSS system which just meets the pfd limit of -105 dB(W/(m²•MHz)) (for angles of arrival above 25º) defined in No. **S21.16** for the band 37-40.5 GHz is assumed in the remainder of this section for each FSS satellite operating in the 41.5-42.5 GHz band. In order to reach the detrimental interference thresholds for RAS stations operating in the 42.5-43.5 GHz band, the attenuation required for a single FSS satellite at elevation angles above 25° operating in the 41.5-42.5 GHz band, is shown in Table 6-3. These values are given relative to the assumed FSS maximum allowed spectral power flux density (spfd) within the necessary bandwidth at the Earth's surface for a single satellite above a 25° elevation angle.

TABLE 6-3

Calculation of the attenuation required for a single satellite to satisfy the detrimental interference thresholds to the RAS in the 42.5-43.5 GHz band

	Continuum	Spectral Line	VLBI
Assumed pfd Limit (arrival>25°) in FSS band	-105 dB(W/(m²•MHz))	-105 dB(W/(m²•MHz))	-105 dB(W/(m²•MHz))
Assumed pfd Limit in FSS band converted to RAS bandwidth	-75 dB(W/(m²•GHz))[1]	-108 dB(W/(m²•500 kHz))[2]	-165 dB(W/(m²•Hz))[3]
Detrimental threshold level in RAS band	-137 dB(W/(m²•GHz))[1] (Table 1 of Rec. ITU-R RA.769-1)	-153 dB(W/(m²•500 kHz))[2] (Table 2 of Rec. ITU-R RA.769-1)	-173 dB(W/(m²•Hz)) (Table 4 of Rec. ITU-R RA.769-1)
Required Attenuation	62 dB	45 dB	8 dB

[1] Average over the 1 GHz bandwidth used for RAS continuum observations (see Table 1, columns 2 and 8, Recommendation ITU-R RA.769-1).

[2] Average over the 500 kHz bandwidth used for RAS spectral line observations (see Table 2, columns 2 and 8, Recommendation ITU-R RA.769-1).

[3] 1 Hz bandwidth used for RAS VLBI observations (see Table 4, Recommendation ITU-R RA.769-1).

For a GSO satellite, the detrimental level in the table should be more stringent by 15 dB and the required attenuation in the table should be increased by 15 dB. Some administrations feel that the need for this additional 15 dB should be carefully evaluated.

Aggregate interference for a constellation of satellites may be limited to the level specified in Recommendation ITU-R SA.769-1 to protect RAS stations. A statistical approach which takes into account the dynamic aspect of non-GSO satellites could be more appropriate to protect the RAS (see § 6.1.4.2.1). Further studies are required.

If the fixed-satellite service in the band 41.5-42.5 GHz (or some portion thereof) were to be constrained to limit their unwanted emissions in the adjacent 42.5-43.5 GHz band to the levels of attenuation contained in Table 6-3 such constraints would have a significant impact on the development of the FSS systems in this band. The effects of fast moving non-geostationary FSS satellites and multiple-satellite systems considered in conjunction with some assumptions used to derive the values contained in Table 6-1 require further studies within ITU-R.

6.1.4.3 Methods to satisfy the agenda item and their advantages and disadvantages

6.1.4.3.1 Technical and operational measures that may be applied to space stations

The following technical and operational measures may be considered for the fixed-satellite service (space-to-Earth) systems to reduce unwanted emissions (In some instances, constraints that may affect the implementability of these measures are noted.):

a) The use of efficient modulation techniques in combination with spectral shaping provides the lowest unwanted spectral sidebands. Also, it is noted that intermodulation products can be avoided when transponders use a single carrier.

b) Minimize spectral sideband growth from modulator defects, non-linear effects, intermodulation, and frequency conversions.

c) The use of low noise broadband power amplifiers will minimize broadband noise generation in transmitter power amplifiers. This technique is also being currently employed to minimize intra-system interference.

d) The increased use of specific filters, such as those which have very sharp cut-off at the edge of allocation band. The use of such filters may have detrimental effects on the group delay problem for wideband carriers and contribute to spacecraft payload weight.

e) The channelization plan for an FSS system can be done in such a way as to increase the guardband near the top of the allocated band.

f) Spot beam antennas can be used to protect geographic areas where radio astronomy observatories are located. However, studies of this concept within ITU-R are required.

Advantages

- These measures could reduce detrimental interference at RAS stations.

Disadvantages

- The main problem with these measures is that they may be rather costly, in terms of financial costs, additional weight and operational efficiency. This problem will be alleviated somewhat if these features are taken into account in the original design of the FSS system.
- Limits on spurious emissions of future FSS transmitters can be expressed in terms of a spurious spectral pfd at the Earth only if certain parameters are known, i.e. the transmitter power P into the transmission line to the satellite antenna, the gain of the satellite antenna, and the spreading loss to the RAS antenna on Earth. Without knowledge of these satellite parameters, only spurious attenuation levels relative to the maximum pfd at the Earth can be expressed for protection of RAS observations. Thus limits specified as an attenuation relative to the transmitter output on both out-of-band and spurious emissions are inflexible; and if applied alone, are inadequate to protect RAS operations in the 42.5-43.5 GHz band from detrimental interference.
- In the case of a constellation of non-GSO satellites or in the case of GSO satellites which are separated by 10° or less, where the interference configurations vary with time, the aggregate pfd at the RAS antenna could be assessed for some acceptable loss of observing time, provided the specific times of loss could be determined by the RAS system for excision of interference from the observational data.

6.1.4.3.2 Operational and geographical separation measures that may be applied to space stations and to RAS stations

If geographical separation of the FSS footprints and a RAS station, is too restrictive for FSS operations, it could be combined with time-sharing on a scale of several hours, provided FSS channels close or adjacent to the 42.5 GHz band edge may be blanked in footprints on or near a RAS station conducting observations in the 42.5-43.5 GHz band. This method requires the directional radiation pattern of the transmitting satellite antenna, and therefore the unwanted spectral pfd at Earth to be known. In this case, RAS stations could notify FSS operators about observing periods in the 42.5-43.5 GHz band in advance, so that unwanted emissions in appropriate footprints could be suppressed below the detrimental level. It should be noted that the number of RAS stations around the world operating in the 42.5-43.5 GHz band is small.

Time-sharing with the FSS on time-scales ranging from milliseconds to hours may be feasible for some types of radio astronomy observations at some radio astronomy stations, but would not be generally applicable. Frequent observations of SiO maser lines to obtain pointing accuracy may prevent time-sharing at some RAS stations. In cases of time-sharing, the aggregate level of unwanted emissions from space stations should not exceed the Recommendation ITU-R RA.769-1 detrimental thresholds for more than some acceptable percentage of the observing time.

Advantage

- These measures could reduce detrimental interference at the RAS stations.

Disadvantage

- Restricted scheduling of RAS observations results in highly inefficient uses of radio telescopes and sacrifices science. Levels of unwanted emission in the side lobes of satellite transmitters which illuminates a radio astronomy antenna outside the intended footprint can be predicted for high gain reflector antennas, but not necessarily for a phased array satellite antenna, which may produce additional unwanted emissions by intermodulation. Therefore, the requirements for geographical separation between Earth footprints defined by phased array satellite antennas and RAS antennas may be difficult to predict, and may therefore not be practicable for some FSS systems. Systems with a large number of satellites could render impractical the possible mitigation technique of mutually exclusive scheduling of FSS transmissions and RAS observations. Considering the potential number of RAS stations in this band, time-sharing on the time-scale of a few hours may severely constrain the FSS operation.

6.1.4.3.3 Measures that may reduce the susceptibility of RAS stations

RAS susceptibility to the aggregate of emissions above 42.5 GHz which may be reduced by:

- reducing side-lobe levels of RAS antennas;
- pointing the RAS antenna such that the 38° cone of gain greater than 0 dBi does not include any satellite (10° cone for GSO satellites); and
- excising interference in the receiver and/or in the data.

Advantages

- These measures could reduce detrimental interference at the RAS stations.

Disadvantages

- Reducing RAS antenna side-lobe levels is generally not feasible for existing antennas.
- Pointing the RAS antenna cones of avoidance away from satellites may be practical only if there is a small number of satellites operating in the band. Restricted pointing of RAS antennas results in inefficient uses of radio telescopes and may not be practicable.
- Excising interference in the receiver and/or in the data, is equivalent to lost observing time, and should not exceed some acceptable percentage of the observing time.

6.1.4.4 Regulatory and procedural considerations

The technical work for Resolution **128 (WRC-97)** has not been completed. WRC-2000 may consider retaining a suitably modified Resolution **128 (WRC-97)** for the next ITU-R study period in order to provide an opportunity to complete the studies initially ordered by WRC-97.

6.1.5 Resolution 129 (WRC-97) "Criteria and methodologies for sharing between the fixed-satellite service and other services with allocations in the band 40.5-42.5 GHz"

At WRC-97, new co-primary allocations to the FS and the FSS were made in the 40.5-42.5 GHz band. The FSS allocation was for the space-to-Earth direction in Regions 2 and 3 and in certain countries in Region 1; the FS allocation was for all three ITU Regions. Resolution **129 (WRC-97)** invited the ITU-R to undertake, as a matter of urgency, studies of appropriate criteria and methodologies for sharing, including power flux-density limits, between the FSS and the other services with allocations in the 40.5-42.5 GHz band.

6.1.5.1 Summary of technical studies

As noted in § 6.1.2.1 above, there is a strong interest worldwide from both the fixed-satellite service and the fixed service communities for access to spectrum in the 37.5-42.5 GHz range. Sharing between the two services has been shown to be technically feasible, particularly where the FS and/or the FSS would not rely on the ubiquitous deployment of terminals.

6.1.5.1.1 Downlink power flux-density for non-GSO FSS

A number of studies have been carried out, leading to draft new Recommendation ITU-R [Doc. 4-9/1008], (submitted to RA-2000).

The results of studies conducted in the ITU-R of known and proposed non-GSO FSS systems, and of known and proposed P-P and P-MP FS systems, indicate that maximum allowable values of power flux-density of -115/-105 dB(W/(m^2•MHz)) at the surface of the Earth would be adequate to protect terrestrial services from non-GSO FSS networks in the frequency band 40.5-42.5 GHz. Studies supporting this conclusion are summarized in Annex 1 of draft new Recommendation ITU-R SF.[Doc. 4-9/1008].

6.1.5.1.2 Downlink power flux-density for GSO FSS

Previously, studies within the ITU-R had not allowed conclusions to be drawn as to the adequacy of the current power flux-density limits for the band 40.5-42.5 GHz to protect terrestrial services from GSO FSS satellites.

When considering a single geostationary satellite operating at maximum allowable power flux-density levels of -115/-105 dB(W/(m^2•MHz)), the in-line interference level (I/N) at an FS receiver with a 33 dBi antenna is -21 dB when the FS receiver is at a 0 degrees elevation angle, and -5 dB when the FS receiver is at a 10 degrees elevation angle.

In order to meet the long-term interference criterion, I/N = -10 dB, the separation angle between the FS receiver and the GSO arc should be no less than 2.5°. In any FS system deployment, a small percentage of links may point at the GSO arc. For those point-to-point FS systems that do not implement any orbital avoidance, the FS receiver could experience interference above the long-term interference criterion when the separation angle from the GSO arc is less than 2.5º. Arc avoidance is not generally applied to most FS applications in this band, but this and other potential mitigation approaches have not been fully studied.

Some administrations have concluded that the current ITU power flux-density limits of -115/-105 dB(W/(m^2·MHz)), as currently specified in Article **S21** for FSS systems in the band 40.5-42.5 GHz, are adequate to protect the FS from GSO FSS networks in the band 40.5-42.5 GHz.

On the basis of studies carried out by one administration, some administrations had concluded that in the case of interference from a fully populated arc of GSO satellites, the aggregate interference into the FS receiver at 10° elevation angle exceeds the long-term interference criterion for a large range of azimuths. Furthermore, these administrations had also concluded that in the band 40.5-42.5 GHz, for an FS receiver at 10° elevation, a power flux-density level of – -135/-125 dB(W/(m^2•MHz)) would ensure that the long-term criterion would be met for all azimuths. In this case it was concluded that this could preclude operation of GSO FSS systems. Some administrations believe that further ITU-R studies and the appropriate pfd values for the GSO FSS systems will be required. Other administrations believe that these ITU-R studies are not required.

On the subject of power flux-density limits for GSO FSS satellites to protect fixed service systems in the 40.5-42.5 GHz band, some administrations provided results of recent studies directly to CPM99-2. Based on these studies, some administrations proposed the following power flux-density mask as a compromise intended to adequately protect the fixed service without unduly constraining the FSS in this band (see Table 6-4).

TABLE 6-4

pfd limits for GSO FSS in the band 40.5-42.5 GHz

Power flux-density limit in dB(W/(m^2•MHz))	Angle of arrival δ above the horizontal plane
-120	$0° \leq \delta < 5°$
$-120 + (\delta - 5)$	$5° \leq \delta < 15°$
$-110 + 0.5 (\delta - 15)$	$15° \leq \delta < 25°$
-105	$25° \leq \delta$

6.1.5.1.3 Separation distance between the FS transmitter and the FSS receiver

The ITU-R is developing new recommendations on the methodology to determine separation distances between non-GSO FSS earth stations and FS stations.

In one study, addressing the band 40.5-42.5 GHz, it was shown that the coordination distances between fixed service transmitters and certain types of non-GSO fixed-satellite service earth-station receivers is relatively small, ranging from 0.1 km and 23 km (depending on the off-axis angle and the FS transmit antenna characteristics). The study also indicated that if the FS transmit off-axis angle is greater than or equal to 5°, the coordination distance between the two services would be less than 1 km. However, the actual separation distance between the FS transmitters and FSS receivers depends on the off-axis separation angle, FS transmit power density, FSS minimum operational elevation angle, and terrain topography.

6.1.5.2 Methods to satisfy the agenda item

On the basis of studies conducted in the ITU-R of known and proposed non-GSO FSS and FS systems, it is concluded that power flux-density limits of -115/-105 dB(W/(m^2•MHz)) in the band 40.5-42.5 GHz at the surface of the Earth would be adequate to protect terrestrial services from non-GSO FSS networks.

Two methods to satisfy the agenda item were identified.

Method A

Method A is to adopt the agreed power flux density limits in draft new Recommendation ITU-R SF.[Doc. 4-9/1008] for non-GSO FSS (as mentioned above), and is to adopt the following pfd limits developed at CPM99-2 for GSO FSS in the band 40.5-42.5 GHz (see Table 6-5).

TABLE 6-5

pfd limits for GSO FSS in the band 40.5-42.5 GHz

Power flux-density limit in dB(W/(m^2•MHz))	Angle of arrival δ above the horizontal plane
-120	$0° \leq \delta < 5°$
$-120 + (\delta - 5)$	$5° \leq \delta < 15°$

-110 + 0.5 (δ - 15)	15° ≤ δ < 25°
-105	25° ≤ δ

Advantages

- These pfd limits allow access to the band for both services without undue constraints on either service, and provides the consequential benefit of more efficient use of spectrum.
- These pfd limits would facilitate the deployment of GSO and non-GSO FSS applications to earth terminals with small receive antennas, and would not unduly constrain the deployment of most P-MP HDFS systems.
- No further studies are required and a decision could be made at WRC-2000.

Disadvantage

- Some stations in the HDFS may potentially be constrained.

Method B

Since the sharing issues between the FS and the FSS in the 40.5-42.5 GHz range have not been fully resolved, solutions could take the form of power flux-density limits that vary among band segments. Method B would build upon the conclusions reached with regard to non-GSO FSS power flux-density limits, and support the development of a comprehensive sharing approach for the 37.5-42.5 GHz band that includes provision for FS systems and both non-GSO FSS and GSO FSS systems. This method connects the 40.5-42.5 GHz band with the 37.5-40.0 GHz band (see § 6.1.2.3.2) and envisions a solution would encompass the entire 37.5-42.5 GHz range. Under this approach, the conclusions reached with regard to non-GSO FSS power flux-density limits are not sufficient to resolve in full the sharing situation between the FSS and the FS in this band.

Advantages

- The result of such different limits would encourage the development of ubiquitous, high-density FS and FSS applications in different portions of the band, and would require only minor modifications to the existing FSS allocations to obtain global co-primary FS and FSS allocations in the 37.5-42.5 GHz band.
- Depending on frequency bands and pfd limits proposed under this method, a decision on the pfd limits in particular frequency bands may be taken at WRC-2000.
- Provides a global sharing approach that is equitable and allows for future growth of both services.

Disadvantages

- May have some impact on the fixed service in administrations that have made FS assignments in this frequency range.

6.1.5.3 Regulatory and procedural considerations

Regulatory and procedural means to resolve the sharing situation between FS and FSS terminals in the 40.5-42.5 GHz range may take a number of forms, including possible modifications to Table **S21-4** and associated notes.

****

6.2 Agenda item 1.5 (Resolution 122 (WRC-97)

"to consider regulatory provisions and possible additional frequency allocations for services using high altitude platform stations, taking into account the results of ITU-R studies conducted in response to Resolution **122 (WRC-97)**"

*Resolution **122 (WRC-97)** "Use of the bands 47.2-47.5 GHz and 47.9-48.2 GHz by high altitude platform stations in the fixed service and by other services"*

A new telecommunication concept using High Altitude Platform Stations (HAPS) for providing FS operations was officially recognized by WRC-97. WRC-97 has made provisions for operation of HAPS in the 47.2-47.5 GHz and 47.9-48.2 GHz bands. An appropriate definition for the HAPS was added to No. **S1.66A**.

Resolution **122 (WRC-97)** requests that technical studies to be conducted to ascertain the extent to which sharing of the designated bands is feasible between systems using HAPS in the FS and systems in the FS, FSS and MS and to ascertain the requirements to protect the RAS in the 42.5-43.5 GHz and 48.94-49.04 GHz adjacent bands from spurious emissions.

6.2.1 Summary of technical and operational studies, including a list of relevant ITU-R Recommendations

6.2.1.1 Sharing between FS systems using HAPS and other conventional FS systems

Study results have been presented which indicate, that in the WRC-97 designated bands at 47.2-47.5 GHz and 47.9-48.2 GHz, sharing between fixed service systems using HAPS and other conventional fixed service systems in the same area will be difficult unless appropriate interference mitigation techniques are developed and implemented. The studies were based on scenarios using worst-case conditions and it has been recognized that further studies are required before any definite conclusions can be reached.

ITU-R studies have also resulted in the development of a draft new Recommendation ITU-R F.[Doc. 9/1017] presenting a set of preferred characteristics for one proposed HAPS-based system at 47.2-47.5/47.9-48.2 GHz, and a draft new Recommendation ITU-R F.[Doc. 9/1018] providing path loss calculation techniques for use in coordinating HAPS-based fixed service operations at 47.2-47.5/47.9-48.2 GHz. These two draft Recommendations are submitted to RA-2000 for approval.

The agenda for the WRC-2000 also recognizes the need for possible additional frequency allocations for radiocommunication services using HAPS. Description of a system for operation in the range 18-32 GHz has been proposed since the 47 GHz bands are more susceptible to the rain attenuation in certain areas. Preliminary sharing considerations using bands within the above range have been presented in terms of parameters such as required separation distance between the system using HAPS and other systems in the fixed service. Ongoing studies indicate that the technical concept of Dynamic Channel Assignment (DCA), which is one of the mitigation techniques, could be very effective in the case that the band allocated for FS is applied to HAPS uplink. Further study including the use of mitigation techniques will be required in the next ITU-R study period.

6.2.1.2 Sharing between FS systems using HAPS and FSS systems

A draft new Recommendation ITU-R SF.[4-9/1005] (submitted to RA-2000 for approval) has been developed which indicates that under certain deployment scenarios, HAPS-based systems and FSS systems employing 2.4 metre diameter antennas, or antennas with equivalent performance can share HAPS designated bands 47.2-47.5 GHz and 47.9-48.2 GHz. Further study is required to fully assess the implications of these scenarios but the indications are that separation distances from a maximum of about 20 km down to a minimum of less than 1 km are feasible if the operation of the FSS earth station is constrained to the rural coverage area (RAC) of the HAPS. The inner edge of this coverage area is approximately 80 km from the nadir of the HAPS.

Sharing with systems in the FSS using the bands 19 and 29 GHz has also been preliminarily studied. In this study, a HAPS-based system is assumed to operate in reverse band working mode (in relation to the FSS allocation). Studies have also considered other frequency bands for possible pairing with either the 19 or 29 GHz band. This study showed that, under certain operational constraints, these systems may have positive potential for sharing the bands with GSO FSS earth stations which are not deployed ubiquitously. It should be noted that there are plans to ubiquitously deploy GSO and non-GSO earth stations in some portions of these bands. In this situation it is anticipated that coordination between ubiquitous earth stations and HAPS user terminals would be difficult. A national or regional allocation to HAPS in the 19 and 29 GHz bands would reduce the deployment flexibility of FSS earth stations in those countries where such an allocation is made. Studies are required for assessment of:

– interference into GSO and/or non-GSO satellite systems;
– aggregate interference between multiple HAPS systems and multiple GSO or non-GSO satellite systems;
– mitigation techniques to enhance the possibility of frequency sharing;
– impact across international borders.

In relation to the above ongoing study items, the preliminary results indicate that interference from a HAPS-based system into a non-GSO system could be small enough under certain typical conditions. The studies present a methodology and calculated example results on required separation distance of HAPS airship and HAPS ground station from international borders regarding study items of impact across international borders. Furthermore, those results indicate that interference mitigation and operation techniques such as footprint offset, limitation of operational elevation angle, improvement of radiation pattern of on-board HAPS antennas, shielding effects of HAPS airship envelope, dynamic channel assignment and the combination of them could significantly improve the deployment flexibility of FSS earth stations.

It is anticipated that, on a national or regional basis, spectrum bandwidth equivalent to that already designated for HAPS at 47-48 GHz range would be needed to satisfy the requirement described above.

In particular areas for climatic and other related considerations it is not practicable to use the 47-48 GHz band for the deployment of HAPS systems. It has been concluded that in many Region 3 countries alternative spectrum allocation below that band is necessary to reap the benefits of this emerging technology. Thus the feasibility of identifying appropriate spectrum in the 18-32 GHz range, taking account of the above considerations should now be studied as a matter of urgency. These studies should be continued as a complement to the ongoing studies being carried out under Resolution **122 (WRC-97)**. Accordingly, Resolution **122 (WRC-97)** will need to be extended until WRC-02/03 and modified, *inter alia*, at WRC-2000 to provide for the framework for the ITU-R studies.

6.2.1.3 Radio astronomy uses of the 48.94-49.04 GHz and 42.5-43.5 GHz bands

The 48.94-49.04 GHz band is used to observe the CS molecule and its isotopes. The 42.5-43.5 GHz band is used for sensitive observations of the extended continuum emission of radio sources and also contains several lines associated with the SiO molecule. These lines are listed among the radio-frequency lines of greatest importance to radio astronomy (Recommendation ITU-R RA.314).

The detrimental interference level for single dish observations in the 48.94-49.04 GHz band is -209 dB(W/(m^2·Hz)) (Table 2, Recommendation ITU-R RA.769-1). For continuum observations at 43 GHz, the detrimental threshold level for single dish observations is -227 dB(W/(m^2·Hz)) (Table 1, Recommendation ITU-R RA.769-1). This level also provides adequate protection for spectral line observations in this band. VLBI observations are considerably less sensitive to interference than observations with single dish telescopes. Table 4 of Recommendation ITU-R RA.769-1 indicates the detrimental interference level for VLBI stations operating in the 42.5-43.5 GHz and in the 48.94-49.04 GHz bands as -173 dB(W/(m^2·Hz)) and -172 dB(W/(m^2·Hz)), respectively.

The following ITU-R Recommendations are relevant to the protection of the RAS in the 42.5-43.5 GHz and 48.94-49.04 GHz bands:

Recommendations ITU-R RA.611, RA.1237, RA.517 and M.1316.

6.2.2 Analysis of the results of studies

6.2.2.1 Mitigation of detrimental interference to a RAS station from a HAPS

Appendix **S3**, Table II gives the spurious emission limits applicable to HAPS, in terms of attenuation relative to the mean power supplied to the antenna in a reference bandwidth of 1 MHz. Detrimental interference levels to the radio astronomy service are, on the other hand, specified in Recommendation ITU-R RA.769-1 in terms of pfd levels at the radio astronomy antenna. The attenuation required by Appendix **S3** for a representative HAPS transmitter, (12 dBW power/cell, 300 MHz transmitter bandwidth/cell and 38 dBi gain towards the RA antenna, located some 150 km away) is about 55 dB in a 1 MHz reference band. The additional attenuations needed to reach the radio astronomy detrimental threshold levels are calculated to be 24 dB and 42 dB in the 48.94-49.04 GHz and 42.5-43.5 GHz RAS bands, respectively. Protection from the aggregate of the illuminating and adjacent cells may require additional attenuation.

The geographical separation between the radio astronomy antenna and the HAPS, the power and the spectral roll-off of the HAPS transmitter, and the gain of the HAPS antenna directed towards the radio astronomy site, and a series of other parameters that depend on each individual situation must be known, to establish what mitigation measures may be required in each situation.

Additional studies are expected in ITU-R regarding a possible methodology to mitigate potentially detrimental interference from a HAPS-based system to RAS and other services in the 18-32 GHz range.

6.2.2.2 Interference mitigation techniques and regulatory considerations

Administrations may protect RAS stations operating in the 43 and 49 GHz bands from detrimental interference through regulation tailored to the requirements of each individual situation, where a HAPS may be near a RAS antenna. A number of techniques may be used in the design of a HAPS system to prevent or reduce the spurious interference into radio astronomy sites to acceptable levels. These include: antenna design, signal and modulation design, and filtering of the radio-frequency signal before transmission.

Filtering needed to reduce out-of-band emission, can be achieved with a raised cosine filter, which can be implemented either with SAW filters alone, or with a combination of digital (baseband) and analogue filtering using SAW filter(s). SAW filter techniques are extremely flexible: any linear bandpass filter may be synthesized, with arbitrary amplitude and phase, limited only by line width and crystal size. Typically single-phase unidirectional transducer (SPUDT) type SAW filters can attenuate out-of-band emission by up to 60 dB, with a passband flatness of less than 0.5 dB peak-to-peak. With another 16 dB attenuation at the first side lobe of the QPSK power spectral density curve, a 75 dB reduction of the out-of-band emission is readily achievable.

If additional filtering is required to meet specific spurious-interference incidents, waveguide filters can be implemented in the beams of HAPS that require such filters. Finally, if further mitigation is, required, HAPS could reduce the level of spurious emissions at RAS antennas by avoiding service cells near a RAS antenna, or reducing the gain of multiple service antennas toward a RAS antenna.

6.2.2.3 The potential use of HAPS in the frequency bands above 3 GHz allocated exclusively for terrestrial radiocommunications

Systems using HAPS (HAPS-based system) for terrestrial applications in bands above 3 GHz have a potential applicability to various services such as high-capacity communications and Earth observation (note that the option for the provision of IMT-2000 services using HAPS is dealt with under agenda item 1.6). Since the HAPS airship is located at lower altitude compared with the satellite, the transmission delay and path loss in the HAPS-based system is smaller than in the satellite systems. Therefore, it would easily bring about size reduction of communication terminals and realization of high capacity communications.

A HAPS-based system has flexible design possibilities such as number of airships, service area and offered services and applications, so as to fit the area size of land and the status of the infrastructures construction in each country. Therefore, each country can define and operate service items such as offered applications, communication fee and service area, based on the designed system.

Further studies within ITU-R are needed to allow HAPS systems in additional bands above 3 GHz exclusively allocated for terrestrial radiocommunications. It is also important that regulatory considerations should also be envisaged.

These concepts have the following advantages and disadvantages:

Advantages

- Since the HAPS equipment is located on an object at an altitude of 20 to 50 km, the visible area from the HAPS equipment would be within one country or include neighbouring countries, which is narrower than that of the satellite system. Therefore HAPS-based systems could operate in terrestrial radiocommunication if the agreement of neighbouring countries visible from the HAPS station could be obtained.
- The concept would enable flexible domestic operation of a HAPS-based system as in terrestrial radiocommunication and enhance the wide applicability of the HAPS-based system.

Disadvantages

- This concept would have the potential for effectively extending the use of HAPS to all terrestrial frequency bands above 3 GHz. ITU-R studies to date have concentrated on the WRC-97 designated bands, 47.2-47.5 GHz and 47.9-48.2 GHz. Studies for other frequency bands are ongoing, but have not been adequately progressed within ITU-R in order to fully assess the impact on the requirements of non-HAPS-based systems.

6.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

It is concluded that it is technically feasible to protect the RAS in the 42.5-43.5 GHz and 48.94-49.04 GHz bands, from spurious emissions from HAPS operating in the 47.2-47.5 GHz and 47.9-48.2 GHz bands, through appropriate protection measures.

Based on the results of sharing studies, appropriate measures should be implemented to protect the RAS in the 42.5-43.5 GHz and 48.94-49.04 GHz bands from HAPS operating in the 47.2-47.5 GHz and 47.9-48.2 GHz bands.

6.2.4 Regulatory and procedural considerations

Coordination distances may need to be developed between radio astronomy sites and HAPS. Regulatory provisions, based on such coordination distances, may need to be developed to establish coordination procedures between radio astronomy sites and HAPS in the 47 GHz bands.

In order to continue studies at 47 GHz and to accelerate studies with the objective of determining the feasibility of identifying additional spectrum for the HAPS below 47 GHz and specifically in the 18-32 GHz range, Resolution **122(WRC-97)** could be modified as per the example attached in Annex 1.

****

6.3 Agenda item 1.8

"to consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz, including their coordination with other services allocated in these bands"

6.3.1 Summary of technical and operational studies

The bands 3 700-4 200 MHz and 5 925-6 425 MHz are currently allocated on a primary basis to both the FS and the FSS, as well as to the mobile service (MS). The FS uses these bands primarily for trunk point-to-point systems, with typical capacities of 34 Mbit/s and above. The FSS uses these bands primarily for fixed earth stations operating in GSO satellite networks.

Earth stations on board vessels (ESVs) can provide wideband services to cruise liners, passenger ships, naval vessels, seismic research and petroleum exploration vessels and other deep draft vessels. ESVs are therefore essentially mobile by nature and as such pose a new interference risk to 6 GHz fixed links.

Preliminary ITU-R studies carried out at 6 GHz have addressed the development of protection and coordination methods. Analyses are under way to define a minimum distance, beyond which an in-motion ESV will not cause unacceptable interference to existing and future fixed systems operating in the 6 GHz band. These analyses generally agree on how to calculate this minimum distance. However, there is disagreement on assumptions and technical parameters to be used in this calculation.

Since MS systems are generally less sensitive to interference from ESVs than FS systems, the text below will focus on the FS systems only. In addition, the 4 GHz band will not be treated, where the FS systems have the potential to cause interference to ESVs.

6.3.2 Analysis of the results of studies

Using the minimum distance beyond which an in-motion ESV will not cause unacceptable interference as a reference, three operational modes have been identified:

i) operation in-motion beyond a specified distance from land;

ii) operation where the vessel is not moving;

iii) operation of the ESV while the vessel is in motion within the specified distance of land.

Based on error performance requirements for the FS, the ITU-R studies have proposed methods for determining the minimum distance that will be necessary in order to protect the FS from unacceptable interference from an in-motion ESV. The minimum distance calculations depend on the interference criteria chosen, whether Automatic Transmit Power Control (ATPC) will be implemented in FS systems, the predicted number of potential interference exposures from ESVs, and the discrimination angle between the ESV and the fixed service receiver. These studies and some additional studies provided to the CPM illustrated the range of minimum distance values that are possible using certain assumptions.

Some of the proposed technical constraints applied to ESVs in the above studies are:

Minimum diameter of ESV antenna:	2.4 m
Minimum elevation angle of ESV antenna:	10°
Maximum necessary bandwidth per vessel:	2.346 MHz
Maximum ESV transmitter power spectral density at the input to the antenna:	17 dB(W/MHz)

Given that vessels are subject to roll, pitch and yaw motions, severe interference could occur within the FSS. Therefore, the tracking accuracy of the ESV antennas should be constrained to 0.2 degrees, regardless of the sea conditions. The half-power beamwidth of 1.5 degrees required to protect adjacent satellites is consistent with the minimum antenna diameter of 2.4 m mentioned above.

The studies that have been conducted in ITU-R have illustrated that the values for the minimum distance are principally affected by the interference criteria required to protect the fixed service and the number of passages per unit time by vessels equipped with earth stations. Based on different values for these assumptions, the results of these preliminary studies yielded a range of values for the minimum distance from 100 km to 540 km. It should be noted that studies submitted to the CPM by some administrations suggested values for the minimum distance of 150 km to 370 km. However, agreement has not been reached on a single minimum distance figure. Further ITU-R studies are required on the ranges and a single minimum distance value.

It should be noted that the specified distance would be calculated for a moving vessel with a speed of 10 knots (approximately 18.5 km/hr). This speed is considered to be representative. If the vessel were stationary then larger distances would be necessary.

6.3.3 Methods of satisfying the agenda item

Several methods were considered with respect to the type of service under agenda item 1.8, because the status of ESV is not defined and does not clearly fall within the functional description of the FSS. Some proposals considered that the service should be in the maritime mobile-satellite service. However, the ESVs operate in bands allocated to the fixed-satellite service.

The different approaches have different jurisdictional implications with respect to all administrations involved. Resolving these implications is a complex legal matter, which WRC-2000 should take into account but may not be competent to resolve.

6.3.3.1 Option 1

Should WRC-2000 wish to introduce the use of ESVs in these bands, agenda item 1.8 can be satisfied by incorporation of the necessary technical and operational constraints on the operation of ESV terminals in the 3 700-4 200 MHz and 5 925-6 425 MHz bands as well as associated methods to protect the fixed service and to ensure its growth, and to protect other systems within the FSS. This may be accomplished by appropriate footnote references to a Resolution that sets forth these constraints as well as regulatory requirements, as discussed in § 6.3.4.

Given the need for more detailed discussion and analysis regarding the assumptions and technical parameters that are used in the calculation of the minimum distance, it is suggested that an administrative value could be adopted for the minimum distance from the coast if WRC-2000 adopts a related regulatory solution. This interim value would apply only until the next WRC and requires validation or modification to reflect the results of technical studies to be accomplished during this period.

A self contained Resolution that addresses and clarifies responsibilities and conditions, including facilitation of bilateral agreements between administrations, for the operation of ESVs within the Radio Regulations could be considered by WRC-2000 as an interim provision.

6.3.3.2 Option 2

Alternatively, the Conference could decide to make no change to the existing Radio Regulations. In this case the ESV terminals would only be able to continue to operate under **S4.4**. The reason for this is the amount of detailed legal and technical work that would have to be done, and the complexity of the treaty status provisions of two international instruments (the Radio Regulations and the United Nations Convention on the Law of the Sea (UNCLOS)) including treatment of fixed stations on off-shore structures and platforms outside the territorial sea.

6.3.4 Regulatory and procedural considerations

The regulatory environment concerning the operation of radiocommunication facilities from stations beyond land boundaries, at sea or in the air, is very complex and depends on the type of radiocommunication service, the location of the station and even the type of communications traffic involved.

If there is an agreement that some regulatory solution is necessary then this should be based on setting a distance limit that is compatible with UNCLOS and which is compatible with the distances indicated with the interference assessment.

In view of the above when the specified distance is defined, a resolution should specify:

- that there are three modes of operation for ESVs:
  - operation where the vessel is not moving;
  - operation in-motion beyond specified distance from land;
  - operation of the ESV while the vessel is in motion within the specified distance of land;
- that in-motion ESV operation is limited to beyond a minimum specified distance from the coasts and that means should be established to cease emissions within this distance, unless prior agreement has been obtained from the concerned administrations.

This text provides example regulatory text whereby earth stations on vessels may be allowed to operate in these bands without a specific allocation by the addition of an appropriate footnote following the precedent set in footnotes RR **S5.485** and **S5.492**.

Provided that requirements on minimum tracking accuracy and maximum beamwidth were included in the relevant footnote or an equivalent, it is believed that no other regulatory provisions would be necessary concerning frequency sharing with other systems within the FSS.

Introducing ESVs in these bands without restrictions would mean that the coordination procedures of **S9.17** and **S9.18** would have to be applied between these stations and terrestrial stations. However, this need could be fulfilled by the appropriate provisions of a resolution. Text for an example resolution ("Resolution **ZZZ**") is provided in Annex 2 to this chapter.

Introducing ESVs on a secondary basis would mean that this type of application would be secondary to other FSS earth stations, which is probably not appropriate.

Introducing ESVs with a footnote in Article **S5** providing for the protection of and the flexibility for the fixed service would avoid this difficulty. Such an example footnote could be worded in the following way:

"In the frequency bands 3 700-4 200 MHz and 5 925-6 425 MHz, transponders on space stations in the fixed-satellite service may be used, additionally, by earth stations on vessels. Such use is subject to the provisions specified in the procedures of Resolution **ZZZ**."

If the Conference decides to take no action with respect to modification of the Radio Regulations to provide for this application then such earth stations on vessels would only be able to continue to operate under **S4.4**.

****

6.4 Agenda item 1.12

"to consider the progress of studies on sharing between feeder links of non-geostationary-satellite networks in the mobile-satellite service and geostationary-satellite networks in the fixed-satellite service in the bands 19.3-19.7 GHz and 29.1-29.5 GHz taking into account Resolution **121 (Rev.WRC-97)**"

*Resolution **121 (Rev.WRC-97)** "Continued development of interference criteria and methodologies for fixed-satellite service coordination between feeder links of non-geostationary satellite networks in the mobile-satellite service and geostationary-satellite networks in the fixed-satellite service in the bands 19.3-19.7 GHz and 29.1-29.5 GHz"*

6.4.1 Summary of technical and operational studies

A draft new Recommendation ITU-R S.[Doc. 4/42(Rev.1)] on mitigation techniques has been prepared addressing mitigation techniques. This Recommendation includes the topics of adaptive power control, high gain antennas, geographic isolation, site diversity and link balancing.

In addition the Recommendation addresses coordination. The results of these studies are summarized below.

6.4.1.1 Power control

The use of adaptive uplink power control may be used to maintain system performance during times of increased levels of interference. Recommendation ITU-R S.1255 recommends that networks employing adaptive uplink power control should transmit signals at the lowest possible power level to mitigate interference between GSO/FSS networks and feeder links of non-GSO/MSS networks.

6.4.1.2 High gain antennas

Restricting the GSO earth station minimum antenna size to 1.0 m results in interference levels below the currently proposed aggregate criteria for the LEO-A MSS network feeder links. The interference level is generally higher for the MEO case than the LEO case. For a 1.8 m GSO earth station antenna the interference criteria are exceeded in all links.

6.4.1.3 Geographic isolation

As indicated in CPM Report to WRC-97, maintaining a minimum latitudinal separation of 2º between competing GSO/LEO earth stations is required to reduce the interference to acceptable levels. In the GSO/MEO case, separations greater than 2º in latitude (225 km) are required to reduce the interference to acceptable levels.

Further, it has been shown that the geographic separation of the earth stations of two systems, combined with the use of high gain antennas, would be more effective in mitigating interference than either of the two techniques separately. Geographic isolation down to 60 km is possible with these techniques.

6.4.1.4 Site diversity

Site diversity is the use of an alternate earth station located far enough away from the primary site to provide sufficient antenna discrimination to maintain acceptable interference levels. Its use as an interference mitigation technique depends on the non-GSO MSS space station antenna beamwidth. For example, to be effective in mitigating interference between a LEO-B feeder-link network and a GSO/FSS network (GSO-13) in the 20/30 GHz bands, earth station diversity would require that the LEO-B satellite antennas be so large as to be impractical.

6.4.1.5 Link balancing

The concept of link balancing refers to the design of non-GSO FSS links to reflect the need to mitigate the effects of uplink transmissions from GSO FSS earth stations. In the case of uplink transmissions from non-GSO MSS earth stations, the GSO receive signal is protected because of the distance involved. However, this is not the case for the uplink of the non-GSO MSS earth station vis-à-vis interfering transmissions from the GSO FSS. To "balance" the transmission environment, the non-GSO MSS earth station carries larger fixed uplink margins to protect itself from the GSO.

6.4.1.6 Coordination

To date the studies conducted by ITU-R indicate that geographic isolation provides the best solution to coordination between non-GSO MSS feeder links and the GSO FSS systems. Typically, there are relatively few non-GSO MSS feeder link earth stations in a system dispersed over a wide area. Within such an area, the non-GSO MSS earth station will require less spectrum than the GSO FSS, thus permitting the additional use of either frequency isolation and/or polarization isolation to achieve satisfactory coordination.

6.4.1.7 Satellite diversity

The use of satellite diversity has been considered as a mitigation technique to avoid main beam-to-main beam interference by switching traffic to an alternative satellite. This technique has a number of system design and network operational implications which network operators have to consider before implementing it. The constellation design is determined by how best to accommodate the service links and may not provide visibility statistics such that satellite diversity is possible.

6.4.2 Method to satisfy the agenda item

The above sections are considered to cover the requirements of Resolution **121 (Rev. WRC-97)** and thus satisfies the agenda item. It is suggested that Resolution **121 (Rev. WRC-97)** could now be suppressed.

6.4.3 Regulatory and procedural considerations

The agenda item may be dealt with through ITU-R Recommendations rather than modification of the RR.

****

6.5 Agenda item 1.14 (Resolution 123 (WRC-97))

"review the results of the studies on the feasibility of implementing non-GSO MSS feeder links in the 15.43-15.63 GHz in accordance with Resolution **123 (WRC-97)**"

*Resolution **123 (WRC-97)** "Feasibility of implementing feeder links of non-geostationary satellite networks in the mobile-satellite service in the band 15.43-15.63 GHz (space-to-Earth) while taking into account the protection of the radio astronomy service, the Earth exploration-satellite (passive) service and the space research (passive) service in the band 15.35-15.4 GHz"*

6.5.1 Summary of technical and operational studies

Studies conducted subject to Resolution **123 (WRC-97)** dealt with two aspects:

1) demand for allocation to non-GSO MSS feeder links in the band 15.43-15.63 GHz (space-to-Earth);
2) feasibility of implementing non-GSO MSS feeder links in the band 15.43-15.63 GHz (space-to-Earth) regarding protection of RAS, EESS (passive) and SRS (passive) operating in the band 15.35-15.4 GHz.

6.5.1.1 Demands in frequency resource for non-GSO MSS feeder links

Frequency bands in the ranges 5-29 GHz are allocated for non-GSO MSS network feeder links subject to Article **S5**. Accommodation analysis based on ITU-R data for non-GSO MSS networks in the concerned frequency bands showed a high planned usage intensity for all of the bands. Furthermore the analysis revealed that operation in a part of the bands is significantly difficult and sometimes impossible due to imposed limitations.

To define practical usefulness of the frequency resource available for operation of non-GSO MSS feeder links, a quality analysis for current allocations was conducted.

The conducted analysis of current frequency band allocations for non-GSO MSS feeder links and intensity of their employment confirms demand for the frequency resource related to the allocations in the band 15.43-15.63 GHz (space-to-Earth) and shows that the band 15.43-15.63 GHz (space-to-Earth) offers potential for implementing non-GSO MSS feeder links, although the suitable mitigation techniques would be required to meet the RAS protection criteria.

6.5.1.2 Protection of radio astronomy in the band 15.35-15.4 GHz from interference produced by unwanted emissions from non-GSO MSS feeder links operating in the band 15.43-15.63 GHz (space-to-Earth)

Based on Recommendation ITU-R RA.769-1 the level of acceptable interference of -202 dBW is taken as a protection criterion for RAS stations in the frequency band 15.35-15.4 GHz. ITU-R studies have found that in coordination processes between the radio astronomy service and single services or individual systems in such services a provisional figure of no more than 2% should be applied as the acceptable percentage of time, during which interference may be permitted to exceed the threshold levels detrimental to the radio astronomy service.

Based on the above-stated criteria, studies were conducted in relation to interference produced by unwanted emissions from feeder links of two typical non-GSO MSS networks (a LEO-N and a LEO-G as described in Recommendation ITU-R S.1328). Both systems apply additional filtering and use suitable transmitted power levels at the space stations to provide necessary protection of RAS in the band 15.35-15.4 GHz.

The analysis showed that interference produced by unwanted emissions from non-GSO MSS space stations (feeder links) to a RAS station in the band 15 GHz would not exceed the acceptable levels, allowing the 2% percentage of time criterion, in the case of both separate and joint operation of the two systems studied. No other study results, indicating the possibility of unacceptable interference to RAS were obtained.

For non-GSO MSS networks of other types the levels of interference produced could exceed the limits described above. Therefore, taking into account that the number of RAS stations operating in the band 15 GHz is limited and their location is known precisely, the following mitigation techniques could be appropriate and might enable other systems to meet RAS protection criteria:

- employing the steered antennas at non-GSO MSS space stations in the band 15 GHz (space-to-Earth) for establishing feeder links;
- maximizing the separation between non-GSO MSS gateway stations and RAS stations to reduce power of potential interference to RAS stations;
- limiting operational elevation angles at non-GSO MSS gateway stations;
- reducing emitted power when passing through the visibility zone of a radio telescope;
- use of substantial filtration to minimize out-of-band emissions in the band 15.35-15.4 GHz.

Maximum effectiveness would be obtained in integrated employment of different mitigation techniques.

6.5.1.3 Protection of EESS and SRS passive sensors in the band 15.35-15.4 GHz from interference produced by unwanted emissions from non-GSO MSS feeder links operating in the band 15.43-15.63 GHz (space-to-Earth)

Recommendations ITU-R SA.515-3, ITU-R SA.1028-1 and ITU-R SA.1029-1 were taken as a basis for studies of the problem.

The studies showed that the worst-case interference scenario for sharing between passive sensors and non-GSO MSS feeder links would be an interference to passive sensors as produced by the Earth's surface reflecting non-GSO MSS feeder-link emissions in space-to-Earth direction.

The results of the conducted estimations show that the requirements for protection of EESS and SRS passive sensors in the band 15.35-15.4 GHz from interference produced by unwanted emissions from non-GSO MSS feeder links operating in the band 15.43-15.63 GHz (space-to-Earth) would be met with the margin of over 50-60 dB.

6.5.2 Methods to satisfy the agenda item and their advantages and disadvantages

The conducted studies comply with the Resolution **123 (WRC-97)** provisions completely and hence cover all issues related to the agenda item concerned. Taking into account that Resolution **123 (WRC-97)** has attained the assigned objectives and aims, it would be appropriate to suppress it at WRC-2000.

The studies conducted show that for existing systems it should be feasible to implement non-GSO MSS feeder downlinks in the band 15.43-15.63 GHz taking into account the protection requirements for RAS and other passive services in the band 15.35-15.4 GHz. Providing that existing non-GSO MSS feeder downlinks systems planning to use the band are able to do so, no disadvantages are foreseen.

However, for future non-GSO MSS systems using the space-to-Earth allocation at 15.43-15.63 GHz substantial mitigation techniques would be required to adequately protect the RAS from harmful interference. It could be concluded that because of high levels of suppression of out-of-band emissions required, use of the band 15.43-15.63 GHz for space-to-Earth feeder links may be limited to use of non-GSO MSS satellite networks for which advanced publication information has been received by the Bureau prior to WRC-2000.

6.5.3 Regulatory and procedural considerations

No. **S5.511A** could be modified so that the use of the frequency band 15.43-15.63 GHz by the FSS (space-to-Earth) would be limited to non-GSO MSS networks for which advanced publication information has been received by the Bureau prior to the end of WRC-2000. Such systems will be required to restrict their out-of-band satellite emissions in the band 15.35-15.4 GHz to meet the requirements of Recommendation ITU-R RA.769-1 for 98% of the time. If the WRC-2000 decides that the above-mentioned limitations are acceptable, it might be appropriate to delete the reference to Resolution **123 (WRC-97)** in No. **S5.511A**.

ANNEX 1 TO CHAPTER 6 (SECTION 6.2)

EXAMPLE DRAFT MODIFICATION TO RESOLUTION 122 (REV. WRC-2000)

Use of the bands 47.2-47.5 GHz and 47.9-48.2 GHz by high altitude platform stations in the fixed service and by other services and the potential use of bands below 47 GHz by HAPS in the fixed service

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that the band 47.2-50.2 GHz is allocated to the fixed, mobile and fixed-satellite services on a co-primary basis;

b) that WRC-97 made provision for operation of high altitude platform stations, also known as stratospheric repeaters, within the fixed service in the bands 47.2-47.5 GHz and 47.9-48.2 GHz;

c) that ITU has among its purposes "to promote the extension of the benefit of the new telecommunication technologies to all the world's inhabitants" (No. 6 of the Constitution of the ITU (Geneva, 1992));

d) that systems based on new technologies using high altitude platforms will be able to provide high-capacity, competitive services to urban and rural areas;

e) that the development of any service requires major investment and that manufacturers and operators should be given the confidence to make the necessary investment;

f) that high altitude platform systems are in an advanced stage of development and some countries have notified such systems to ITU;

g) that the Radio Regulations Board issued a provisional rule of procedure concerning notification periods in No. **S11.24/1228** in February 1997;

h) that in spite of the urgency attached to the development of such systems, technical, sharing and regulatory issues should be further studied in order to achieve the most efficient use of the spectrum available for these systems;

i) that technical studies have been undertaken on the characteristics of a HAPS system in the frequency bands 47.2-47.5 GHz and 47.9-48.2 GHz and on the coordination and sharing requirements between HAPS systems and systems in the conventional fixed service and in other services, but that further studies are still in progress on the potential for interference between such systems;

j) that the radio astronomy service has primary allocations in the bands 42.5-43.5 GHz and 48.94-49.04 GHz;

k) that ITU-R study results have been presented which indicate that in WRC-97 designated bands at 47.2-47.5/47.9-48.2 GHz, sharing between fixed service systems using HAPS and other conventional fixed service systems in the same area will require appropriate interference mitigation techniques to be developed and implemented;

l) that No. **S5.552** urges administrations to reserve fixed-satellite service use of the band 47.2-49.2 GHz for feeder links for the broadcasting-satellite service, and that ITU-R studies indicate that high altitude platform stations in the fixed service may share with broadcasting-satellite feeder links;

m) that ITU-R studies in the bands 47.2-47.5 GHz and 47.9-48.2 GHz indicate that sharing between fixed service systems using HAPS and FSS could be feasible under certain limitation, such as geographical separation between HAPS-based systems and FSS earth stations;

n) that since 47 GHz bands are more susceptible to the rain attenuation in certain areas of Region 3, the 18-32 GHz range has been proposed for possible identification of additional spectrum in ITU-R and preliminary studies are in progress for these bands;

o) that the 18-32 GHz range is already heavily used by a number of different services,

resolves

1 to urge administrations to facilitate coordination between high altitude platform stations in the fixed service operating in the bands 47.2-47.5 GHz and 47.9-48.2 GHz and other co-primary services in their territory and adjacent territories;

2 that, on a provisional basis, the procedures of Article S9 shall be used for coordination between satellite systems and high altitude platform systems;

3 to request ITU-R to continue to carry out urgently studies on the appropriate technical sharing criteria for the situations referred to in *considering i)*;

4 to request ITU-R, taking into account the requirements of other fixed service systems and other services, to urgently conduct studies on the feasibility of identifying additional frequencies for the use of HAPS in the fixed service in the range 18-32 GHz;

5 that WRC-02/03 should review the results of these studies and consider refinement of the regulatory provisions that might facilitate a broader application of these high altitude platform technologies,

instructs the Director of the Radiocommunication Bureau

1 that notices concerning high altitude platform stations that were received by the Bureau prior to 22 November 1997, and provisionally recorded in the Master International Frequency Register in accordance with the provisional rule of procedure issued by the Board, shall be maintained;

2 that from 22 November 1997, and pending review of the sharing studies in *considering i)* and review of the notification process by WRC-02/03, the Bureau shall accept notices in the bands 47.2-47.5 GHz and 47.9-48.2 GHz only for high altitude platform stations in the fixed service and for feeder links for the broadcasting-satellite service, shall continue to process notices for fixed-satellite service networks (except for feeder links for the broadcasting-satellite service) for which complete information for advance publication has been received prior to 27 October 1997, and shall inform the notifying administrations accordingly.

ANNEX 2 TO CHAPTER 6 (SECTION 6.3)

Introduction

The text contained in this annex is an example, in support for Option 1, regulatory mechanism provided for the aid of administrations in their preparation for WRC-2000.

EXAMPLE DRAFT RESOLUTION ZZZ (WRC-2000)

Provisions to enable earth stations located on board vessels to operate in fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that there is a demand for global wideband satellite communication services on vessels;

b) that the technology exists that would permit the use of fixed-satellite services (FSS) networks by earth stations on board vessels (ESVs) operating in the 3 700-4 200 and 5 925-6 425 MHz bands;

c) that ESVs have the potential to cause unacceptable interference to the fixed service (FS) systems in the band 5 925-6 425 MHz;

d) that FS systems have the potential to cause interference to ESVs in the 3 700-4 200 MHz band;

e) that ESVs operating in these bands require considerably less than the full bandwidth in this FSS allocation and only a portion of the visible geostationary arc;

f) that there are a limited number of geostationary FSS systems that have global coverage;

g) that in order to ensure the protection and future growth of the FS, the ESV must operate with certain technical and operational constraints;

h) that administrations may authorize radiocommunication stations on off-shore structures and platforms for which they are responsible:

i) that based on appropriate assumptions a minimum distance can be calculated beyond which the ESV will not have the potential to cause unacceptable interference to the fixed service in this band,

noting

a) that operation within the territorial sea is at the discretion of the administration with territorial authority, in which case the relevant procedures of that administration will apply;

b) that operation of earth stations on vessels from specified fixed points at locations outside the territorial sea but for which an administration has territorial jurisdiction is fully within the FSS,

resolves

1 that the administration that issues the radio licence for the use of ESVs in these bands (licensing administration) shall ensure that such stations do not cause unacceptable interference to stations in the fixed service;

2 that licensing administrations shall ensure that ESVs are capable of operating in compliance with the requirements of this Resolution;

3 that operators of ESVs shall comply with the conditions established by the licensing administration(s);

4 that ESVs shall not claim protection from fixed service station transmissions;

5 that any transmissions from ESVs within a distance X km off any given coast shall be based upon the prior agreement of that coastal administration;

6 that the ESV system shall include means of identification and automatic mechanisms to terminate transmissions whenever the station operates outside its pre-authorized geographic (see *resolves* 5) or operational limits;

7 that ESVs shall be equipped so as to enable the licensing administration under the provisions of Article **S18** to verify earth station performance and to accomplish the switch off of the ESV transmission immediately upon request by an administration whose services may be affected;

8 that when ESVs operating beyond the territorial sea but within X km of the coast of an administration fail to comply with the terms required by that administration pursuant to *resolves* 3 and 5, then that administration may:

– request the ESV to comply with such terms or cease operation immediately; or

– request the licensing administration to require such compliance or immediate cessation of the operation;

9 that any licensing authority that licenses ESVs shall agree to maintain at all times a point of contact, which shall be published in a circular of the ITU, that may be contacted by an affected administration seeking assistance pursuant to *resolves* 3 and 5 above.

CHAPTER 7

Other matters

(WRC-2000 agenda items 1.2, 1.3, 2, 4, PP Resolutions and RR No. S5.488)

CONTENTS

Other matters

7.1 Agenda item 1.2

"to finalize remaining issues in the review of Appendix **S3** to the Radio Regulations with respect to spurious emissions for space services, taking into account Recommendation **66 (Rev.WRC-97)** and the decisions of WRC-97 on adoption of new values of spurious emissions for space services taking effect at a future time"

Although not specifically defined in Article **S1**, the term "space services" is taken to be any service which uses "*Space Radiocommunication*" as is defined in Article **S1**.

7.1.1 Summary of technical studies

Appendix **S3** contains tables of maximum permitted spurious emission power levels. Table I contains the values applicable to transmitters installed on or before 1 January 2003 (valid until 1 January 2012), while Table II applies to the transmitters installed after 1 January 2003 and to all transmitters after 1 January 2012. Note 14 of Table II identifies the spurious emissions limits for space services as "design objectives" until after WRC-2000.

In considering Appendix **S3** and Recommendation **66 (Rev.WRC-97)**, "Studies of the maximum permitted levels of unwanted emissions" and in particular its *recommends* 1 and 2, the following five items are addressed with regard to agenda item 1.2:

i) space services spurious emission limits and how they are applied;

ii) the limiting case of a very narrow-band or unmodulated signal in a wideband amplifier operating particularly in the space services;

iii) the special case of spurious emission limits that should not apply in adjacent transponders within the same transmitting system;

iv) amateur earth stations operating below 30 MHz; and

v) an exemption from spurious emission limits for deep-space satellites,

and these items have been studied by ITU-R.

7.1.2 Analyses of the results of studies

ITU-R concluded that there is no further need for the "design objectives" qualification for space services limits and that at this time, they believe that no changes to the attenuation values or the reference bandwidth for space services are applicable. This reflects its view to transform these "design objectives" into a regulatory limit.

ITU-R discussed the option of distinguishing between two types of earth station, viz., mobile and fixed earth stations, while keeping identical values for spurious emission levels, as a means of indicating that it may be appropriate to have different levels at some future time. It was concluded to maintain this concept within the ongoing studies of ITU-R, but in the meantime, no specific change to categories contained within Table II of Appendix **S3** is suggested. Likewise, it was noted that the requirements for downlink transmissions from the space transmitters of MSS are different from those of FSS and BSS, and again, this concept will be retained under study within the ITU-R.

ITU-R considered the situation of amateur earth stations which use the same transmitting equipment for communication to both space and terrestrial stations but which currently fall into two different categories of spurious emission limits. Amateur earth stations use the same transmitting equipment as amateur stations, both below and above 30 MHz, and there is no reason for the same terrestrially-based equipment to be subject to different spurious emission requirements when transmitting to amateur space stations. Below 30 MHz, amateur stations in the amateur service, use 43 + 10 log(PEP), or 50 dB, whichever is less stringent in determining the applicable spurious limit. Above 30 MHz, Appendix **S3** currently requires amateur earth stations to fall into the "All services" category of Table II, viz., up to 70 dBc suppression, which causes amateur earth stations to have more restrictive limits than other earth stations. Furthermore, longer-term studies should address the appropriate use of spurious emission spectral density limits (dBs) in this case as an alternative to dBc, as some amateur earth stations use SSB emissions. A new footnote in Table II applied against "Space services (earth stations)" would be appropriate for such case. At the same time, it was noted that footnote 12) to Table II of Appendix **S3** gives no value to the Table II service category of "Amateur services operating below 30 MHz (including with SSB)" and may, in fact, add to the ambiguity since it gives no information or instruction. This particular service category includes all amateur stations in any event. Therefore, it would be appropriate to delete the reference to footnote "12)" as noted here.

ITU-R has studied the case where spurious emissions from one transponder fall on a frequency at which a companion transponder is transmitting, on the same satellite, into the same service area. This situation is particularly aggravated when both transponders illuminate the same footprint on Earth. A separate self-explanatory Headnote **11*ter*** to Appendix **S3** has been drafted to cover this case. Appropriate text on the point is suggested in § 7.1.4.

Studies have concluded that there is no reason for *Deep Space* spacecraft, as defined by the RR, to have any spurious emission limits specified. An exemption for these spacecraft is based on the fact that *Deep Space* spacecraft emissions are so weak that only unusual communications equipment, using massive antennas and very low noise cooled amplifiers, can detect even the fundamental signal, let alone any spurious emissions. A consequential suggestion is made to exempt such *Deep Space* spacecraft from requirements for spurious emission limits.

Studies have revealed difficulties with specifying spurious emission limits for very narrow-band or unmodulated space service signals. Therefore, ITU-R concluded that very narrow-band or unmodulated transmissions, where practical application of the term "necessary bandwidth" may be difficult to apply in practice in determining the domain of spurious emissions, need special consideration. A separate self-explanatory Headnote **11*bis*** to Appendix **S3** has been drafted to cover this case. Appropriate text on the point is suggested in § 7.1.4.

7.1.3 Methods to satisfy the agenda item and their advantages and disadvantages

7.1.3.1 Limits regarding space services

To transfer the spurious emission limits currently included in Appendix **S3** for space services as "design objectives" into regulatory limits.

Advantage

- Final adoption of the spurious emission limits currently included in Appendix **S3** for space stations of the space services will provide a general degree of protection for other systems, while not placing an unreasonable burden on the space services given the current state of technology and cost effectiveness of implementing systems.

Disadvantage

- Studies on the differences between vulnerable service requirements and unwanted emission levels that are feasible, and on possible approaches to solve the differences, are ongoing.

7.1.3.2 Other relevant issues

Special consideration is necessary for amateur earth stations, very narrow-band or unmodulated signals in a wideband amplifier operating particularly in the space services, Deep Space space stations, and companion transponders operating within the same satellite.

Advantage

- The advantage of the suggested changes for these four cases is to avoid unnecessary expense in applying limits that are not necessary and for which additional protection need not be afforded.

Disadvantages

None.

7.1.4 Regulatory and procedural considerations

To indicate unambiguous adoption of the space services spurious emission limits currently designated "design objectives", Footnote 14 in Table II of Appendix **S3** can be deleted.

To adequately recognize the case of very narrow-band and unmodulated signals, particularly for the space services, a new Headnote ***11bis*** to Appendix **S3** can be added to read as follows:

> "As an emitted signal becomes more and more narrow (to the limiting case of an unmodulated carrier with theoretical necessary bandwidth of zero), the application of the term "necessary bandwidth" as used in determining the region where spurious emission limits apply to space services, becomes more and more difficult. In the limit, ±250% of necessary bandwidth (generally recognized as establishing the region beyond which spurious emissions are defined), approaches zero. Beacon and other unmodulated signals, such as those used in uplink and downlink circuits in the control and tracking of satellites, are examples of cases where it is difficult to apply, in a practical manner, the term "necessary bandwidth" in determining where out-of-band emissions end, and spurious emissions begin. Pending further studies and definitive action by a future world radiocommunication conference, to specify the region where spurious emission limits apply for transmitters using amplifiers to transmit essentially an unmodulated signal (or a signal with very small bandwidth), the amplifier bandwidth is taken to be the necessary bandwidth (in calculating the regions where spurious emissions will apply)."

To avoid unnecessary design and operational requirements for adjacent transponders in the same transmitting system, a new Headnote ***11ter*** to Appendix **S3** can be added as follows:

> "For satellites employing more than one transponder, and when considering the limits for spurious emission as indicated by Headnote **11** to Appendix **S3**, spurious emissions from one transponder may fall on a frequency at which a companion, second transponder is transmitting or in the guard band between two transponders. In these situations, the level of spurious emission from the first transponder is well exceeded by fundamental emissions of the second transponder or by out-of-band emissions into the guard band. Therefore, the limits of Appendix **S3** should not apply to those spurious emissions on a satellite which fall either within the bands where there are transmissions from different transponders, on the same satellite, into the same service area or within the guard bands between the different transponders."

To avoid "amateur earth stations" having to comply with spurious emission limits different from "amateur stations", a new footnote in Table II, to the "Space services (earth stations)" category, can be added as follows:

> "Amateur earth stations operating below 30 MHz are in the service category "Amateur services operating below 30 MHz (including with SSB)"."

In the Table II service category of "Amateur services operating below 30 MHz (including with SSB)," delete the reference to footnote "12)," retaining footnote 12) itself as well as retaining reference to footnote 12) in the two Table II categories, "SSB from mobile stations" and "Services operating below 30 MHz, except space, radiodetermination, broadcast, those using SSB from mobile stations, and amateur."

To cater for space stations intended to operate in *deep space* (defined in **S1.177**) which have essentially undetectable spurious emissions in every case, a new footnote in Table II, to the "Space services (space stations)" category, can be added as follows:

> "Space stations, intended to operate in *deep* space (defined in **S1.177)** are exempt from spurious emission limits."

7.1.5 Issues not directly related to space services as specified in agenda item 1.2

If considered to be within the competence of WRC-2000, revision of the text in Appendix **S3** regarding radiodetermination (radar) systems will correct the implication that radars are immediately subject to spurious emission limits under Section I, and rightly provide for measurement of radar spurious emissions in the radiated field, allowing for consideration of the benefits of antenna selectivity.

These two separate spurious emission issues related to radar systems have arisen in the context of Appendix **S3**, but are obviously not directly related to space services as specified in agenda item 1.2. However, changes are suggested for Appendix **S3** to bring it into alignment with radar-related ITU-R studies and conclusions, if WRC-2000 agrees to consider these issues.

7.1.5.1 Inclusion of spurious emission limits for radar systems

Appendix **S3** as adopted by WRC-97 includes a paragraph addressing measurement methods for radar systems. The inclusion of this paragraph by WRC-97 immediately under Section I of the Appendix implies that the current spurious emission limits also apply to radar systems. ITU-R has recommended changes to Appendix **S3** that would indicate that spurious emission limits apply to radar systems only under Section II.

It is concluded that WRC-97 may not have intended to include radar systems under the spurious emission limits of Section I of Appendix **S3**. Radar systems have been exempted from the limits in Section I because the required measurement methods had not been determined. The measurement methods now provided in Recommendation ITU-R M.1177 pertain to the spurious emission limits in Section II, which apply to radar transmitters installed after 1 January 2003 and to all radar transmitters after 1 January 2012.

To clarify the possible misunderstanding regarding the applicability of spurious emission limits for radar systems, ITU-R recommends modifying No.6 in Section I of Appendix **S3** to read as follows:

> Radar systems are exempt from spurious emission limits under this section.~~The measurement methods for radar systems should be guided by Recommendation ITU-R M.1177. For those radar systems for which acceptable methods of measurement do not exist, t~~The lowest practicable power of spurious emission should be achieved.

7.1.5.2 Measurement of radiated emissions

Furthermore, ITU-R has considered modification of Section II of Appendix S3 to indicate that spurious emission levels for radar systems should be based on radiated emissions, and not measured at the transmission line as called for in Headnote 1 to the Appendix. This would ensure that the measured spurious emission levels account for the inherent selectivity of certain radar antennas which are integral to the transmitting system.

ITU-R concludes that some radar antennas, such as slotted arrays and some distributed phased arrays, have inherent selectivity reducing the level of spurious emissions. For this reason, Appendix **S3** should indicate that spurious emissions of radar systems should be based on the radiated field, not the power in the transmission line.

To indicate that spurious emission levels for radar systems should be determined from radiated emissions, ITU-R recommends that a new footnote be added to the "Radiodetermination" service category in Table II of Section II to read as follows:

> "Radiodetermination (radar) system spurious emission attenuation (dB) shall be determined for radiated emission levels, not at the antenna transmission line. The measurement methods for determining the radiated spurious emission levels from the radar systems should be guided by Recommendation ITU-R M.1177."

ITU-R recommends also modifying existing Headnote 8 of Section II, adding the words "or for specific applications, such as radar, where the antenna is designed to provide significant attenuation at the spurious frequencies" at the end of the second sentence.

****

7.2 Agenda item 1.3

"to consider the results of ITU-R studies in respect of Appendix **S7/28** on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services, and take the appropriate decisions to revise this Appendix"

7.2.1 Summary of technical and operational studies

Draft new Recommendation ITU-R SM.[XX], entitled "Determination of the coordination area around an earth station in frequency bands between 100 MHz and 105 GHz", has been developed with a view to providing a single consolidated recommendation covering methods for determining coordination areas. The Recommendation has included revised propagation models (see Recommendation ITU-R P.620-4), has drawn upon the methods contained in Recommendations ITU-R IS.847-1, IS.848-1 and IS.849-1, and used methodologies and parameter values provided by the relevant ITU-R Study Groups.

7.2.2 Analysis of the results of studies

7.2.2.1 Issues addressed by this Recommendation

There is considerable operational experience suggesting that the methods included in Appendix **S7** produce coordination areas of an acceptable size. Steps were taken to ensure that, where their frequency ranges and situations overlap, the Recommendation referred above and Appendix **S7** produce coordination areas similar in size.

This Recommendation will enable the administrations and the BR to determine coordination areas:

- over an extended frequency range from 100 MHz to 105 GHz;
- for transmitting earth stations with respect to receiving earth stations operating in bidirectionally allocated bands;
- for earth stations operating to GSO satellites in inclined orbits;
- for earth stations operating to satellites anywhere within a defined portion of the GSO arc, with or without orbital inclination;
- for mobile earth stations and BSS earth stations (in the non-planned bands) operating within a defined service area;
- using improved methods for the construction of auxiliary contours to assist in the coordination process;
- introducing supplementary contours to assist in the coordination process.

Also, improved methods for dealing with earth stations operating with non-GSO spacecraft were developed. Two methods (time invariant gain and time variant gain) were retained and guidance for their use are given in this Recommendation. The time invariant gain (TIG) method provides ease of implementation, but overestimates the coordination distance. In order to reduce the coordination burden and on the basis of bilateral or multilateral agreements, administrations can use the time variant gain (TVG) method to obtain more realistic results.

7.2.2.2 Issues needing further studies

The following issues need further studies:

- methods considering the cumulative impact in determining the coordination areas for high-density earth stations (fixed and mobile) or based on system parameters representing high density use (fixed and mobile);
- methods to address propagation mode (1) modelling of VHF/UHF frequencies for percentages of time below 1%;
- methods to address propagation mode (1) water vapour density for both radio climatic Zones B and C;
- refinements to propagation mode (2) to address elevation angle dependency and the displacement of the centre of propagation mode (2) contour from the coordinating earth station;
- some system parameter values are missing from the parameter value tables.

Work is continuing in these areas and will need to be incorporated in a future revision to Appendix **S7**. Furthermore, each WRC might make allocation decisions requiring the updating of the parameter tables.

7.2.3 Methods to satisfy the agenda item and their advantages and disadvantages

7.2.3.1 Revision of Appendix S7

With regard to the revision of Appendix S7, the ITU-R identified the following options not necessarily in order of preference:

Method 1

To replace the text of Appendix **S7** with text based on the Recommendation.

Advantages

- To have the essential material from the Recommendation available as a complete and consistent regulatory procedure.
- Will only duplicate material from the Recommendation that has an agreed regulatory status.

Disadvantage

- In order to update Appendix **S7** in the future, it will have to be placed on a future WRC agenda.

Method 2

To replace the text of Appendix **S7** with text based on the Recommendation and to establish a permanent agenda item to update the tables of parameters in Appendix **S7** in response to allocation decisions made at the previous conference.

Advantages

- To have the essential material from the Recommendation available as a complete and consistent regulatory procedure.
- Will only include material from the Recommendation that has an agreed regulatory status.

Disadvantage

- Requires additional permanent item for WRC agendas.

Method 3

To replace the text of Appendix **S7** with text based on the Recommendation and to create a mechanism, via a new WRC resolution, to allow updating of the system parameter values as needed via an "an extraordinary agenda item" to a WRC. This resolution could be based on the format of Resolution **60 (WARC-79)** but would deal with system parameter values instead of propagation issues. In this format, there will be a need to establish mechanisms to facilitate Radiocommunication Assembly consideration of the revised parameter tables and to initiate an extraordinary agenda item on the agenda of the next WRC.

Advantages

- To have the essential material from the Recommendation available as a complete and consistent procedure.
- Will only include material from the Recommendation that has an agreed regulatory status.
- Would be on the WRC agenda only when needed.

Disadvantages

- Requires a modified or new resolution.
- Resolution 60 mechanism to create an extraordinary agenda item has never been used.

Method 4

To replace the text of Appendix **S7** with text based on most of the Recommendation, but to incorporate by reference the parameter tables of the Recommendation since they require frequent updating.

Advantages

- More easily updated since recommendations incorporated by reference are a permanent WRC agenda item.
- Limits the scope of what might be viewed as changeable.

Disadvantages

- To perform the complete procedure, the user will have to go from Appendix **S7** in Volume 2 of the Radio Regulations to the Recommendation in Volume 4.
- Reproduces whole recommendation, duplicating much of what is in Appendix **S7**.
- Limits the ability to update the methods.

Method 5

To incorporate the Recommendation by reference.

This method would simply require within Appendix **S7** an introductory statement to refer to Annex 1 of Recommendation ITU-R SM.[XX], which provides the methods for determining coordination areas, and to Annex 2 of Recommendation ITU-R SM.[XX], which provides the system parameter tables.

Advantages

- More easily updated since recommendations incorporated by reference may be updated at each WRC.
- Would allow dealing with unresolved issues in the near future.

Disadvantage

- While only the system parameter values require regular updating, this approach may lead to the updating of the entire Recommendation becoming a constant ongoing process.

7.2.3.2 Other related issues

In addition to the revision of Appendix **S7**, there would be value in moving information on predetermined coordination distances from Appendix **S5** to Appendix **S7**. When moving the appropriate material to Appendix **S7**, there may also be some value in combining Tables 1 and 2 of Annex 1 of Appendix **S5** and eliminating listing of uses that are not covered by a protected allocation. An example of this combination and correction of the tables dealing with predetermined coordination distances is shown in Annex 1 of Chapter 7.

Advantage

- To facilitate the application by all administrations of the coordination procedures among earth stations and terrestrial stations by having, as much as practicable, all the appropriate material of Appendices **S5** and **S7** relating to the determination of the coordination areas in a single appendix.

Disadvantage

- Relocation of regulatory text from the familiar location.

7.2.4 Regulatory and procedural considerations

If the Recommendation is used to update Appendix **S7**, the following regulatory and procedural implications have been identified:

– Recommendations ITU-R IS.847-1, IS.848-1, and IS.849-1 might no longer be required in Volume 4, pending the results of the WRC.

– References to Recommendations ITU-R IS.847-1, IS.848-1 and IS.849-1 will need to be revised.

– Resolution **60 (WARC-79)** will need to be revised to accurately reference provisions in Appendix **S7** dealing with propagation. (This Resolution provides the opportunity for updating the propagation component of Appendix **S7** via an extraordinary WRC agenda item. See Method 3.) If the opportunity for an extraordinary agenda item for the propagation component is no longer needed the resolution could be suppressed.

– Implications of extending the frequency range below 1 GHz need to be reviewed for Article **S21**.

– Definitions in Article **S1** (**S1.171**, **S1.172**, **S1.173**) need to be reviewed for alignment with the text in the Recommendation.

The following examples show ways to bring the text of the definitions into agreement with the Recommendation.

MOD S1.171 *coordination area:* When determining the need for coordination, ~~T~~the area surrounding ~~associated with~~ an *earth station* sharing the same frequency band with *terrestrial stations* or surrounding a transmitting *earth station* sharing the same bidirectionally allocated frequency band with receiving *earth stations*, outside of which ~~a terrestrial *station* sharing the same frequency band neither causes nor is subject to interfering *emissions* greater than a~~ the permissible level of interference will not be exceeded and coordination is therefore not required.

NOC S1.172

MOD S1.173 *coordination distance:* When determining the need for coordination, the ~~D~~distance on a given azimuth from an *earth station* sharing the same frequency band with *terrestrial stations* or from a transmitting *earth station* sharing the same bidirectionally allocated frequency band with receiving *earth stations*, beyond which ~~a terrestrial *station* sharing the same frequency band neither causes nor is subject to interfering *emissions* greater than a~~ the permissible level of interference will not be exceeded and coordination is therefore not required.

- Additional data are needed in Appendix **S4** to cover all data elements required to determine the coordination area of a particular earth station.

****

7.3 Agenda item 2

"to examine the revised ITUR Recommendations incorporated by reference in the Radio Regulations which have been communicated by the associated Radiocommunication Assembly, in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution **27 (Rev.WRC-97)**"

Resolution 27 (Rev.WRC-97) "References to ITU-R and ITU-T Recommendations in the Radio Regulations"

Resolution 28 (WRC-95) "Revision of references to ITU-R Recommendations incorporated by reference in the Radio Regulations"

7.3.1 Regulatory and procedural considerations

The Radio Regulations have referred to technical and operational material contained in ITU-R (CCIR) Recommendations for many years. Recently though, the concept of using Incorporation By Reference in a more formal context has been the cause of considerable discussion within ITU during WARC-92, WRC-95 and WRC-97. Between WARC-92 and WRC-95 the Voluntary Group of Experts charged with simplifying the Radio Regulations specifically recommended the use concept to satisfy the twin aims of simplifying the Radio Regulations and reducing their volume by replacing many provisions of a technical or operational nature by references to ITU-R Recommendations, i.e., either existing Recommendations or Recommendations constructed for the purpose. Implicit in the concept was that the referenced texts would have the same mandatory character as would the equivalent treaty text in the Radio Regulations.

Thus, to qualify unequivocally as incorporation by reference, a text that is referenced in the Radio Regulations must satisfy the following conditions:

- the introductory language making reference to the text in question must be of a mandatory nature;
- the reference must be explicit, specifying the specific part of the text (if appropriate) and the version or issue number.

These and other principles underlying the concept's application were identified and approved by WRC-95 in Resolutions **27** and **28**.

The implementation of the concept commenced at WRC-95 and progressed further at WRC-97. However, by WRC-97 it was obvious that a large amount of detailed work remained to be done just to ensure that all instances where incorporation by reference was definitely intended had been treated correctly. In addition, there remain a very large number of references to ITU-R Recommendations which, though not intended to be mandatory, were too vague to be of any great value. Resolution **27** was updated at WRC-97 to give guidance on the scope of work required to achieve consistency in all references to ITU-R Recommendations, and some ITU-T Recommendations, whether mandatory, advisory or merely informative.

Some concerns raised by ITU members relate to the need to be aware of which recommendations could be candidates for incorporation by reference into the Radio Regulations. Of equal importance, administrations need to know of any ITU-R Recommendation currently incorporated by reference, which is being (or has been) revised during the current study period. For some administrations, WRC may be the first opportunity to be aware of these recommendations. Many administrations would benefit greatly by being advised as early as possible. Therefore, a mechanism for the early identification should be established.

In accordance with the provisions of Resolution **28 (WRC-95)** and Resolution **27 (Rev.WRC-97)**, each WRC now has to devote time to ensuring that references are up to date because the various Study Groups of the ITU Sectors routinely propose revisions to ITU-R Recommendations that have already been incorporated by reference and, in response to WRC agenda items, generate new Recommendations for incorporation by reference. It was therefore envisaged at WRC-97 to have a standing agenda item for all future WRCs to carry out this essential work.

Several factors have, however, led to the continued usefulness of incorporation by reference being questioned recently. Notably, the concept has failed to provide the practical benefit originally envisaged of simplifying or reducing the volume of the Radio Regulations. In order to satisfy the Rules of Procedure governing WRCs, the Regulations that entered into force on 1 January 1999 now have a fourth volume which contains the Recommendations currently identified as having a mandatory aspect (though many remain to be identified). This also gives rise to problems over the status of the texts incorporated by reference since any texts incorporated by reference have to be published as part of the Radio Regulations in recognition of their mandatory status. However, the texts in question will not have been subject to the full procedures laid down for approval of treaty text at WRCs because the volume of text involved cannot be handled through the usual procedures for approving documentation. (See Annex 2 for a discussion of WRC procedures regarding incorporation by reference.)

The status of incorporation by reference has been discussed during the VGE work and at WARC-92. However, there was no firm conclusion and, despite many requests, no definitive opinion emerged from the ITU legal service as to whether text incorporated by reference is an obligatory part of the Radio Regulations or not. The majority view at WRC-95 was that such texts are obligatory, but still many administrations cannot accept that they have to be treated as an obligatory part of the Radio Regulations.

The legal situation is not the only aspect of status to consider. There is also the structure of the ITU-R Recommendations themselves. Often their intended use was to provide guidance, or even a number of options, and the language used is indeed only advisory, i.e., *"should do...", "may do..."*, etc. Also, the substantive text is usually contained in Annex(es), preceded by introductory text that is superfluous for regulatory purposes. The addition of mandatory text in the Radio Regulations when referring to such Recommendations does not therefore enhance the regulatory status of those texts.

The result is that the complexity of the Radio Regulations does not appear to have been reduced and in fact there is still no firm agreement on the status of provisions employing incorporation by reference are now more confused than before.

Taking all the inputs together, two main options of keeping to the current arrangements or abandoning the concept altogether have been identified coupled with several intermediate possibilities. The range of views presented may be summarized as follows:

1) Retain the present situation and ensure that references to material incorporated by reference are accurate, up to date and appropriate, together with ensuring that other classes of reference are appropriate for the purpose.

2) Eliminate or reduce instances of incorporation by reference by transferring some or all of the incorporated texts explicitly into the Radio Regulations making such changes as necessary to the base Recommendations to ensure regulatory consistency. Under this scheme the remaining non-mandatory references to ITU-R and ITU-T Recommendations would be to the latest version of explicitly identified Recommendations and would only be made for the purposes of supplying necessary guidance or information.

3) Retain the concept but be more selective in its use, possibly limiting mandatory reference only to material developed specifically for a well-defined and agreed purpose within the Radio Regulations or only for stable technical material. Again, references of a non-mandatory nature to the latest versions of Recommendations could be retained for the purpose of guidance and information.

4) Retain incorporation by reference only for material of an operational nature, the maritime and aeronautical services in fact, where differences in legal interpretation would be less contentious since there would be no impact on the decisions of major economic importance that do arise where Recommendations concerning coordination of satellite networks are concerned.

5) Retain incorporation by reference keeping in mind the principles of Resolution **27** and provide administrations with the time to consult with their experts. The Director of the Radiocommunication Bureau would provide to the CPM immediately preceding a WRC a list of ITU-R Recommendations currently incorporated by reference in the Radio Regulations which are being revised for submission to the Radiocommunication Assembly or have been revised and approved through the consultative process of Resolution ITU R-1 during the current study period. This listing would be solely for information to administrations and would not confer any special status to the Recommendations.

In addition, and in order to ensure that the Radio Regulations does contain the complete collection of the ITU-R Recommendations that are incorporated by reference, CPM considers that a more formal mechanism should be adopted via a Resolution at WRC-2000 which would list explicitly all ITU-R Recommendations that are incorporated by reference and which will be published in the Radio Regulations.

Annex 3 shows an example of setting priorities for work under Resolution **27** indexed in order of ITU-R Recommendations. Annex 4 provides one possible approach to improving incorporation by reference. Annex 5 defines several categories of provision making reference to ITU-R Recommendations and then lists those Recommendations by category in the order they are found in the Radio Regulations.

****

7.4 Agenda item 4

"in accordance with Resolution **95 (WRC-97)**, to review the resolutions and recommendations of the previous conferences with a view to their possible revision, replacement or abrogation"

*Resolution **95 (WRC-97)** "General review of the resolutions and recommendations of world administrative radio conferences and world radiocommunication conferences"*

CPM took note of the initial study of the Bureau in response to Resolution **95 (WRC-97)**. In addition to the specific suggestions which were addressed to the Director through some input contributions to CPM, CPM also considers that the BR Report to WRC-2000 on this issue should be amended so as to include cross-references to the relevant sections of the CPM Report to WRC-2000 which treat the issues referred to in the Resolutions/Recommendations that are explicitly or implicitly on the agenda of WRC-2000. Furthermore, and in order to facilitate the activities in response to Resolution **95 (WRC-97)** at WRC-2000, appropriate indication of the concerned Committee/Working Group should be included, where appropriate, based on the available information as to the possible structure of the Conference. Some administrations expressed the view that Resolutions and Recommendations dealing with maritime matters should not be revised or abrogated by WRC-2000 excepting those that are explicitly on the agenda of WRC-2000.

The table below contains a list of Resolutions and Recommendations identified by this CPM as related to the Chapters of its Report.

Resolutions/Recommendations
Chapter 1 - IMT-2000, maritime and aeronautical issues
Resolution **212 (Rev.WRC-97)** "Implementation of International Mobile Telecommunications (IMT-2000)"
Resolution **716 (WRC-95)** "Use of the frequency bands 1 980-2 010 MHz and 2 170-2 200 MHz in all three Regions and 2 010-2 025 MHz and 2 160-2 170 MHz in Region 2 by the fixed and mobile-satellite services and associated transition arrangements"
Recommendation **622 (WRC-97)** "Use of the frequency bands 2 025-2 110 MHz and 2 200-2 290 MHz by the space research, space operation, earth exploration-satellite, fixed and mobile services"
Resolution **346 (WRC-97)** "Protection of distress and safety communications on the frequencies 12 290 kHz and 16 420 kHz from harmful interference caused by these frequencies being used also for non-safety calling"
Resolution **342 (WRC-97)** "Review of new technology to provide improved efficiency in the use of the band 156-174 MHz by stations in the maritime-mobile service"
Recommendation **318 (Mob-87)** "Improved efficiency in the use of the Appendix **S18/18** VHF frequency spectrum for maritime mobile communications"
Chapter 2 - Mobile-satellite and radionavigation-satellite services
Resolution **218 (WRC-97)** "Use of the bands 1 525-1 559 MHz and 1 626.5-1 660.5 MHz by the mobile-satellite service"
Resolution **213** "Sharing studies concerning possible use of the band 1 675-1 710 MHz by the mobile-satellite service"
Resolution **220 (WRC-97)** "Studies to consider the feasibility of using a portion of the band 1 559-1 610 MHz by the mobile-satellite service (space-to-Earth)"
Resolution **214 (Rev.WRC-97)** "Sharing studies relating to consideration of the allocation of bands below 1 GHz to the non-geostationary mobile-satellite service"

Resolution **728 (WRC-97)** "Studies relating to consideration of allocations in the broadcasting band 470-862 MHz to non-geostationary mobile-satellite services"
Resolution **219 (WRC-97)** "Studies relating to consideration of the allocation to the non-geostationary mobile-satellite service in the meteorological aids band 405-406 MHz and the impact on primary services allocated in the adjacent bands"
Chapter 3 – Non-GSO FSS issues
Resolution **130 (WRC-97)** "Use of non-geostationary systems in the fixed-satellite service in certain frequency bands"
Resolution **538 (WRC-97)** "Use of the frequency bands covered by Appendices **30/S30** and **30A/S30A** by non-GSO systems in the fixed-satellite service"
Resolution **131 (WRC-97)** "Pfd limits applicable to non-GSO FSS systems for protection of terrestrial services in the bands 10.7-12.75 GHz and 17.7-19.3 GHz"
Chapter 4 - Space science services and radio astronomy
Resolution **723 (WRC-97)** "Consideration by a future competent world radiocommunication conference of issues dealing with allocations to science services"
Chapter 5 - Appendices **S30** and **S30A**
Resolution **49 (WRC-97)** "Administrative due diligence applicable to some satellite communication services"
Resolution **53 (WRC-97)** "Updating of the "Remarks" columns in the tables of Article **9A** of Appendix **S30A** and Article **11** of Appendix **S30**"
Resolution **73 (WRC-97)** "Measures to solve the incompatibility between the broadcasting-satellite service in Region 1 and the fixed-satellite service in Region 3 in the frequency band 12.2-12.5 GHz"
Resolution **532 (WRC-97)** "Review and possible revision of the 1997 BSS Plans for Regions 1 and 3"
Resolution **533 (WRC-97)** "Implementation of the decisions of the WRC-97 relating to Appendices **S30** and **S30A** to the Radio Regulations"
Resolution **534 (WRC-97)** "Implementation of Annex 5 to Appendix **S30** and Annex 3 to Appendix **S30A** of the Radio Regulations"
Resolution **536 (WRC-97)** "Operation of broadcasting satellites serving other countries"
Resolution **538 (WRC-97)** "Use of the frequency bands covered by Appendices **S30/30** and **S30A/30A** by non-geostationary-satellite systems in the fixed-satellite service"
Recommendation **35 (WRC-95)** "Procedures for modification of a frequency allotment or assignment plan"

Chapter 6 - Fixed and fixed-satellite services
Resolution **126 (WRC-97)** "Use of the frequency band 31.8-33.4 GHz for high-density systems in the fixed service"
Resolution **726 (WRC-97)** "Frequency bands above 30 GHz available for high-density applications in the fixed service"
Resolution **128 (WRC-97)** "Allocation to the fixed-satellite (space-to-Earth) service in the 41.5-42.5 GHz band and protection of the radio astronomy service in the 42.5-43.5 GHz band"
Resolution **129 (WRC-97)** "Criteria and methodologies for sharing between the fixed-satellite service and other services with allocations in the band 40.5-42.5 GHz"
Resolution **133 (WRC-97)** "Sharing between the fixed service and other services in the band 37-40 GHz"
Resolution **134 (WRC-97)** "Use of the frequency band 40.5-42.5 GHz by the fixed-satellite service"
Resolution **122 (WRC-97)** "Use of the bands 47.2-47.5 GHz and 47.9-48.2 GHz by high altitude platform stations in the fixed service and by other services"
Resolution **121 (Rev.WRC-97)** "Continued development of interference criteria and methodologies for fixed-satellite service coordination between feeder links of non-geostationary satellite networks in the mobile-satellite service and geostationary-satellite networks in the fixed-satellite service in the bands 19.3-19.7 GHz and 29.1-29.5 GHz"
Resolution **123 (WRC-97)** "Feasibility of implementing feeder links of non-geostationary satellite networks in the mobile-satellite service in the band 15.43-15.63 GHz (space-to-Earth) while taking into account the protection of the radio astronomy service, the earth exploration-satellite (passive) service and the space research (passive) service in the band 15.35-15.4 GHz"
Chapter 7 - Other matters
Recommendation **66 (Rev.WRC-97)** "Studies of the maximum permitted levels of unwanted emissions"
Resolution **27 (Rev.WRC-97)** "References to ITU-R and ITU-T Recommendations in the Radio Regulations"
Resolution **28 (WRC-95)** "Revision of references to ITU-R Recommendations incorporated by reference in the Radio Regulations"
Resolution **60 (WARC-79)** "Relating to information on the propagation of radio waves used in the determination of the coordination area"
Resolution **95 (WRC-97)** "General review of the resolutions and recommendations of world administrative radio conferences and world radiocommunication conferences"
Resolution **721 (WRC-97)** "Agenda for the 1999 World Radiocommunication Conference"
Resolution **722 (WRC-97)** "Preliminary agenda for the 2001 World Radiocommunication Conference"

7.5 PP Resolutions

The Plenipotentiary Conference (Minneapolis, 1998) adopted the following Resolutions with respect to matters that may need to be addressed by WRC-2000:

- Resolution 85 (COM5/11): "Evaluation of the administrative due diligence procedure for satellite networks adopted by the World Radiocommunication Conference (Geneva, 1997)".
- Resolution 86 (COM5/17): "Coordination and notification procedures for satellite networks".
- Resolution 87 (COM5/19): "Role of the notifying administration in the case of an administration notifying on behalf of a named group of administrations".
- Resolution 88 (COM5/22): "Implementation of processing charges for satellite network filings and administrative procedures".

These Resolutions were transmitted to the Special Committee on Regulatory/Procedural Matters and the CPM for appropriate studies.

7.5.1 Resolution 85 - Administrative Due Diligence

It was noted that the BR is required to submit a report to WRC-2000 on the application of Resolution **49 (WRC-97)**. The BR is requested:

- to separate in its report to WRC-2000 those cancellations of filings that were as a result of the application of Resolution **49** from those that would have been cancelled without Resolution **49** due solely to the date limits in the Radio Regulations;
- make its report available as soon as possible so that administrations are able to judge the effectiveness of the administrative due diligence process;
- to include in its report to the WRC any comments from administrations reflecting any difficulty that they have experienced in the application of Resolution **49**.

7.5.2 Resolution 86 - Improvements to the Satellite Coordination and Notification procedures

7.5.2.1 Date of bringing into use of satellite frequencies

In the present Regulations, the phrase "Date of Bringing into use" is used but there is no definition as to what is meant by this phrase. During the past couple of years this lack of clarity has resulted in some problems. There were two contributions to the SC/CPM suggesting some changes to the appropriate sections in Appendix **S4** and Annex 2 of Appendices **S30** and **S30A**. The intent of this proposal was to clarify what is meant by this phrase and in so doing draw upon some elements of No. **S13.6**. A possible example would be as follows:

> Appendix **S4** Annex 2A, A.2 *a)* - The date (actual or foreseen, as appropriate) of bringing the frequency assignment (new or modified) into use. <u>In the case of geostationary-satellite networks the date of bringing into use denotes the date at which the frequency is brought into regular operation to provide the published radiocommunication service with the technical parameters within the technical characteristics notified to the Bureau.</u> Whenever the assignment is changed in any of its basic characteristics (except in the case of a change in § A.1 *a)*, the date to be given shall be that of the latest change (actual or foreseen, as appropriate).

Some administrations expressed their concern to recommend a definition of the date of operation applicable only to one service, and consider that the matter should be left for further studies.

The original suggestion would have applied to both GSO and non-GSO networks and there were some concerns about the manner in which such changes could be applied in the case of non-GSO networks. The possible application of this type of provision to non-GSO networks has been examined and due to the complexity of this issue for non-GSO networks, this suggestion is now limited to GSO networks.

7.5.2.2 Coordination trigger

At the present time Appendix **S8** (formerly Appendix 29) is used to determine the coordination requirements, and with the increasing complexity of the notices these calculations are very complex. The present procedures of Articles **S9, S11** and the Appendix **S8** calculations require detailed data (Appendix **S4** - previously Appendix 3 data) on the satellite networks.

A possible approach could be that coordination would only be required with those networks that are within a specified orbital separation of the proposed network and having a frequency overlap. The major volume of notices is for the FSS service and perhaps a more simplistic approach should be tried for that service first. This separation angle could be different for the different frequency bands. One submission suggested that as a result of some preliminary studies based on a specific system in certain bands the trigger angles could be in the range of 7-8 degrees with different values for different frequency ranges, however the specific angles mentioned are still under study by ITU-R and therefore have not been considered by the CPM. These studies under way relate to the FSS but a similar concept could be applied to other services, but there has been no detailed study as to what the angles might be. Some concerns were expressed that this concept might not identify possibly affected networks outside the coordination angle. A possible variation was suggested that would permit administrations, if they have networks outside the coordination arc, and can show using Appendix **S5** that this network might be affected to be included in the coordination process as provided for presently by No. **S9.41**. Another suggestion was that administrations should have the right to exclude networks from the coordination process, if those administrations can show using Appendix **S5** that those networks would not be affected. However, one administration expressed concern about this suggestion.

Concerns were expressed as to the impact that such a suggestion may have on the role and workload of administrations especially in developing countries, if an extensive self-identification regime proves necessary to safeguard their interests. There were also concerns that requests for coordination originated through self-identification would be treated with equal status to those identified by the new procedures in the BR.

A suggestion was made to include the service area separation as another factor; however, there were also concerns expressed about including this aspect.

7.5.2.3 Separation of uplink and downlink data

Another suggestion to further simplify the provisions of the Radio Regulations involves the separation of the uplink and downlink in determining the need for coordination. At the present time, the data requirements are complicated by the need to provide strapping tables to cover all of the possible combinations of the uplink and downlink frequencies, however, in the end it is necessary to identify separate coordination requirements for the two directions of transmissions. With the simplified coordination angle triggers it would be possible to treat the uplink and downlink completely separately by looking only at the orbital separation where there is a frequency band overlap and considering the two directions separately. For identifying possible coordination needs outside the coordination arc, there would be considerable simplification in the exchange of data between administrations, if the strapping information is not a part of the data.

Within the current ΔT/T approach there would be considerable simplification under the present process for both the coordination and notification phases if the two directions were treated separately.

This approach could be effected by deleting parts of Section D of Appendix **S4** and with the appropriate consequential changes to Appendix **S8**.

A concern was expressed that the deletion of these strapping data from Appendix S4 may have some other consequences. It was noted that this suggestion relates only to the identification of potentially affected administrations. Specific frequency coordination between administrations would continue to be based on the use of the relevant ITU-R Recommendations.

7.5.2.4 Identification of networks subject to coordination

Under the present procedures, Appendix **S8** (formerly Appendix 29) is used to identify the **networks**, with which coordination is required, but the procedures require the identification of the **administrations** affected and this results in some problems. Under the existing provisions in the application of No. **S9.7** plus others, the BR is required to identify the administrations with which coordination is required. The trigger requirements under Appendix **S8** are based on individual networks. The present practice of the BR is to stop the examination for networks of a particular administration, once one network is identified. This identified network may be an insignificant or very significant problem in the coordination process. In the publications of the BR including the Special Sections and the MR, BR only identifies the administration with no identification of the networks involved. The reasons for including an administration in the coordination requirements are not public, as the networks are not listed. When an administration receives the publication indicating that it is included in the coordination requirements for the network being published, it does not know which of its networks triggered the coordination requirement. It is then necessary for the administrations to agree on which networks will be included. Once the coordination is completed and communicated to the BR, there is no record with BR as to whether a particular network was included in the agreement or not. There are also provisions in Appendix **S5** which state that no coordination is required for a modification if the interference is not increased, but BR has no record as to whether the networks were in fact coordinated in the first place. Some administrations were concerned that this would place an additional burden on the BR, which would benefit only a limited number of administrations. This approach could easily be effected by adding a footnote to No. **S9.36** to indicate that in the case of coordination under Nos. **S9.7**, **S9.8**, **S9.9**, **S9.12** and **S9.13**, BR is required to identify for information purposes the specific satellite networks.

This new approach could be equally applicable if a coordination angle is used for the trigger.

7.5.2.5 Proposed simplifications to Article S9 and Appendix S5

A contribution was received for the simplification of Article **S9** and Appendix **S5** in respect of the coordination between earth stations and terrestrial stations. The simplification is based on the consideration that, for the same situation of interference, up to three different entry points currently exist in Article **S9** and the associated provisions in Appendix **S5**, leading to essentially identical procedures, with some of them being in addition incomplete or even non-existent:

- Nos. **S9.15** and **S9.17** both address the coordination of an earth station with terrestrial stations, respectively in the bands covered by No. **S9.11A** (Resolution **46**) and in other bands at frequencies higher than 1 GHz;
- Nos. **S9.16, S9.18** and **S9.19** all address the coordination of a transmit terrestrial station with a receive earth station, respectively in the bands covered by No. **S9.11A** (Resolution **46**), in

bands not covered by No. **S9.11A** nor by No. **S9.19** at frequencies higher than 1 GHz, and in the bands covered by No. **S9.11**, i.e. allocated to unplanned BSS. This leads to an extremely complex definition of the scope of each of these provisions, whilst it would be equivalent to have only one provision referring to different sections of Appendix **S7**.

Based on the above considerations, this contribution concluded that the simplification would be achieved by the merging of Nos. **S9.15** and **S9.17** on one hand, and Nos. **S9.16**, **S9.18** and **S9.19** on the other hand, the intent of this contribution was to address several situations where no coordination currently exists. The method to effect coordination has been developed by the ITU-R under agenda item 1.3 of WRC-2000.

It was noted, however, that this merging may cause difficulty in the coordination procedures and place additional costs on administrations and terrestrial station operators and possibly earth station operators and the Bureau, and therefore that no attempt should be made to merge these provisions. It was also noted that aspects of coordination not presently specified in the RR should be left to negotiation between administrations. Two contributions were of the view that the bringing into use of a non-GSO network can take much longer than a GSO network, and a FS network can be brought into use much faster than either type of satellite network. The existing Radio Regulations were constructed to, and do achieve, a reasonable balance among all these factors.

It was also noted that the proposed merging would need to take into account that coordination of typical FSS earth stations under **S9.15** is not allowed under **S9.17**.

7.5.2.6 Coordination among typical earth stations and terrestrial stations

A contribution was received addressing the possible application of the current procedures of the Radio Regulations in the case where typical earth stations and terrestrial stations are used. It was noted that several agenda items of WRC-2000 (1.3, 1.4, 1.5, 1.8, 1.13 and 1.20) could be expected to address this issue, in particular in the cases involving high-density applications.

The use of spectrum under these circumstances is a three dimensional problem covering the spectrum itself, but also the geographical area and the time-frame in which this spectrum is to be used. The current restrictions to specific earth stations in the procedures of Nos. **S9.17**, **S9.17A** and **S9.18** and associated provisions in Article **S11** allow full use of these three dimensions to enable equitable access to the spectrum resources.

A concern was expressed that if typical earth stations were to be used generally instead of specific ones (with the obvious exception of mobile stations, which evidently cannot be anything else than typical), the process may become a one shot exercise in which the major parameters which allow to equitably access spectrum resources between neighbouring administrations, i.e. time and geographic distributions, may be lost, thereby allowing a one shot pre-emption of common resources by one service in one country over the entire border area with another country at the detriment of the other services in this country.

On the other hand, the protection of services like BSS or BS require the regulatory possibility to protect typical stations. One contribution reviewed the way in which this situation is addressed in the current Radio Regulations and concluded that, with some adjustments to the current provisions in Article **S9**, an adequate response could be given to the legitimate requirements of the administrations.

The Radio Regulations provide an example of how this difficulty has been resolved in the past in the case of the broadcasting-satellite service (BSS) in the frequency bands shared with terrestrial services with equal primary status:

- in the frequency bands subject to Appendix **S30** Plans, Article 6 of Appendix **S30** gives a super-primary status to the BSS with respect to terrestrial services by protecting the entire service area of the BSS assignments in the Plan against interference from terrestrial stations, from the date the BSS assignment is entered in the Plan;
- in the frequency bands not subject to a Plan, Resolution **33** does not provide any specific protection to non-planned receiving BSS earth stations. However, **S9.19** through the criteria contained in Appendix **S5** does provide for the coordination of transmit terrestrial stations with respect to an earth station of the BSS when the pfd of the terrestrial station exceeds the permissible level at the edge of the service area.

On this example, this contribution concluded that one solution found in the past in the case of coexistence between BSS and terrestrial services in certain frequency bands, was equivalent to downgrading the status of the terrestrial services. However, the pfd is not a hard limit, but a coordination threshold. If an administration with a terrestrial station wishes to exceed this pfd, it can coordinate with affected administrations. Further, in the Appendix **S30** bands, as pending modification to the Plans are not protected from terrestrial stations until they become a part of the Plans (which can be a lengthy process), it seems that the terrestrial stations may actually have an advantage.

Article 6 of Appendix **S30A** provides a somewhat different approach to protect terrestrial services from interference caused by the transmit feeder-link earth stations in the Plan: as in the case of Appendix **S30**, the procedure is intended to protect the entire service area from constraints arising from the need to share with terrestrial services. However, if the procedure of Article 6 of Appendix **S30A** is initiated by an administration intending to bring a terrestrial station in operation, the administration with the feeder-link assignment in the Plan has to indicate the exact coordinates of the feeder-link earth station which may cause interference into the terrestrial station. Short of that, the terrestrial station will have to be protected in the future. In Region 2, an additional provision is that the feeder-link earth station is also entered in the Plan following this process. However, due to the ubiquitous nature of BSS receive earth stations, this approach, which requires knowledge of the location of each earth station, would not be practical.

Another view is that if BSS receive earth stations would be protected anywhere in their service area, there will be a situation where BSS in many cases precludes easy implementation of future terrestrial services within a geographical area; thus, this situation does not present an equitable balance between services.

It was noted that both WRC-95 and WRC-97 contemplated the coordination of typical earth stations in bands subject to **S9.11A** and **S9.19**.

In the context of the use of typical stations, the discussions on the possible merging of the various provisions in Article **S9** relating to coordination between earth stations and terrestrial stations discussed in section 7.5.2.5 above identified the following problem areas:

1) The merging of No. **S9.15** into No. **S9.17** would require the identification of specific earth stations in certain bands allocated to the FSS and would place a significant burden on administrations to provide specific earth station information when the earth stations are expected to be ubiquitous and are authorized on an area basis. In any case, the coordination of either typical or specific earth stations, both of which are included in **S9.15**, cannot be completed without the agreement of the neighbouring administration. One administration expressed the need for WRC to consider the notification of typical earth stations coordinated under **S9.15**. Another administration believes that the existing notification provisions must be retained.

2) In situations where No. **S9.17** currently applies, terrestrial-station operators would not have earth station information to use in designing their terrestrial links if specific earth stations are not coordinated. Additionally, if an administration coordinates assignments for typical earth stations but never notifies assignments for specific earth stations, terrestrial-station operators would not have earth station information to use in designing their networks. Due to lack of earth station information, coordination of terrestrial stations may become a trial-and-error method.

3) The benefit of coordinating receiving terrestrial stations is not evident. If an administration coordinates a receiving terrestrial station within the coordination area of typical earth stations, the administration responsible for the typical earth stations could agree to coordination, subject to the terrestrial stations accepting interference, and not be required to provide specific earth station information. This could present additional work for the Bureau if its assistance is required to effect coordination.

4) Taking the specific situation of the broadcasting-satellite service (BSS), Article 6 and Annex 3 of Appendix **S30** recognizes the need to protect BSS receiving earth stations within the entire BSS service area. The development of No. **S9.19**, and the associated criteria in Appendix **S5**, recognizes that the BSS needs to be protected as typical earth stations.

One administration expressed concern that the coordination of typical earth stations may lead to decreased efficiency in the use of the spectrum.

7.5.2.7 Possible modifications to Article S11 in order to resolve anomalies in relation to recording of assignments in the Master International Frequency Register

The simplification process conducted by the VGE, WRC-95 and WRC-97 has led to merging into Articles **S9** and **S11** various provisions previously included in different Articles (11, 12, 13 and 14), Resolutions (**33** and **46**) and Appendices (**S30** and **S30A**) of the Radio Regulations, noting that certain provisions of Article **S9** (e.g. **S9.17**) are suspended with respect to Appendices **S30** and **S30A**.

With a few exceptions, the notification and recording procedures of Article **S11** are now common for most situations. One significant difference in the treatment of the various types of assignments remains however, in relation to recording of assignments for which the relevant coordination procedure under Article **S9** could not be concluded successfully.

The CPM received a contribution on this aspect of Article **S11** that concluded that there would be significant advantage to harmonize the recording provisions under these circumstances. In particular, in the cases of assignments subject to coordination under Nos. **S9.12** to **S9.16** (formerly Resolution **46**), the lack of harmonization of the recording provisions results in a situation where the coexistence between GSO and non-GSO systems and between non-GSO earth stations and terrestrial stations may lead to blockage of the recording process by the first user of the frequency band.

In the cases where the coordination of an assignment under Nos. **S9.7, S9.17, S9.17A** and **S9.18** could not be concluded successfully, Article **S11** foresees a two-step approach to record this assignment in the Master Register:

- In the first step, the Bureau conducts an examination of the probability of harmful interference (No. **S11.32A** for No. **S9.7** and No. **S11.33** for Nos. **S9.17, S9.17A** and **S9.18**). If this examination is favourable, the assignment is recorded.

- In the second step, should the examination under the first step be unfavourable, the assignment may be resubmitted and recorded if the Bureau is informed that it has been in use, together with the assignment which was the basis for the unfavourable finding, for at least four months without any complaint of harmful interference being made (No. **S11.41**). After this second step, the assignment remains under the Damocles of No. **S11.42**, i.e. any harmful interference has to be ceased if it occurs into the assignments which was the basis of the unfavourable finding.

This approach, which follows the pattern previously used under Articles **11** and **13** since 1971, for GSO networks ensures that an administration cannot block the recording process, hence the establishment of the rights of other administrations, for undue reasons.

In particular, the entry points corresponding to Resolution **46** (Nos. **S9.12** to **S9.16**) are not covered by these provisions. This means that in case of disagreement in the coordination process under any of Nos. **S9.12** to **S9.16**, recording in the Master Register is not possible.

In the case of Nos. **S9.12** and **S9.13** (coordination between non-GSO and GSO satellite systems) the coordination in non-planned bands is triggered by bandwidth overlap only, and no coordination threshold or method currently exists in these cases. This means that disagreeing to a coordination request, without any technical reason, is sufficient to prevent the access to frequencies of subsequent satellite systems (GSO or non-GSO), even if in practice no interference would occur. However, ITU-R is working to establish interference criteria in these cases.

It was noted that this procedural gap could be resolved by appropriate changes to Articles **S9** and **S11**.

Three possible suggestions for dealing with this issue were identified as follows:

a) keep No. **S11.32A** applicable to only GSO (**S9.7**);

b) expand No. **S11.32A** to make it applicable to both the GSO and non-GSO situations;

c) suppress No. **S11.32A** with the consequence that network frequencies that are not coordinated could be recorded directly in the Master Register under the conditions of No. **S11.41**.

Each of the above suggestions has implications for GSO and non-GSO networks which require further study.

A similar approach was suggested with respect to No. **S11.33**.

7.5.2.8 Publication of coordination requests

A contribution was considered illustrating regulatory changes that might be made to Article **S9** to facilitate accelerated availability of coordination request data.

The data submitted to the BR pursuant to No. **S9.30** is not required to be sent directly to administrations. Thus, according to the current Radio Regulations, most administrations will not see the coordination request until it is published by the BR after the complete examination (No. **S9.35**). and identification of administrations with which coordination must be effected (No. **S9.36**). The CPM considered an alternative to the existing process that would provide for the BR publishing this data after an expedited examination for conformity with No. **S11.44**. Thereafter, the BR would continue to examine the data to complete the rest of its obligations; this proposal makes no change to the scope of the BR's examination. However with this approach, administrations would be able to review data several months earlier than at present.

Having coordination data available as early as possible relative to when the data are assembled by the requesting administration may facilitate early identification of coordination issues and permit preliminary consultations to occur pending completion of the BR's examination. Given that satellite payload design decisions have to be made early in the manufacturing process, the early identification of issues that may affect those designs may help reduce incompatibilities and facilitate coordination.

A concern was expressed that publishing the coordination data in a two-step process might result in additional work for the BR. This disadvantage may, however, be tempered by the possibility that the "second" publication may be much smaller than the initial publication - it could be as small as a report by the BR listing the administrations with which coordination must be effected. Additional concern over this approach relates to uncertainty over the status of the coordination data published at the first step. If changes to the data emerge during the BR's examination, they would need to be taken into account in any ensuing coordination. Some administrations were of the opinion that no useful conclusions could be reached on the basis of raw data and that the uncertainties thus introduced could actually reduce the efficiency of the coordination process. In addition it will lead to additional non-justified efforts and cost for the BR.

If some improved process were to be adopted by WRC-2000, it may be appropriate to include some means to treat the backlog of pending coordination requests. This might be accomplished by a resolution that details transitional measures for the dissemination of coordination requests pending in the backlog. Some views were expressed that this might also be facilitated by electronic means, whereas other views expressed concern about the use of electronic means only.

7.5.2.9 Coordination procedures for non-GSO/BSS (sound)

In the bands 2310-2360 MHz and 2535-2655 MHz, there are allocations to groups of countries to the BSS (sound) in accordance with No. **S5.393** and No. **S5.418**, respectively.

Some administrations were of the view that there are no provisions in the Radio Regulations that preclude the use of non-GSO BSS (sound) in the above bands.

At the present time the use of a space station for the broadcasting-satellite service is to be applied under the coordination procedure of Resolution **33** and Article **S9** depending on the date of receipt for the API or the request for coordination.

The coordination procedure between space stations in the broadcasting-satellite service and terrestrial stations in Resolution **33** is specified with no distinction between broadcasting-satellite services employing geostationary-satellite orbit (GSO) and non-geostationary-satellite orbit (non-GSO).

However, while the provisions of Nos. **S9.11** and **S9.19** specify the coordination procedure between "a space station" and terrestrial services, Table S5-1 in Appendix **S5** indicates the procedure between "GSO/terrestrial". In order to resolve this inconsistency, the reference "GSO/terrestrial" in the first column of Table S5-1 of Appendix **S5** for Nos. **S9.11** and **S9.19** could be modified as "GSO, non-GSO/terrestrial".

In addition to this inconsistency, it was noted that there is no coordination procedure applied for non-GSO/BSS (sound) in respect of GSO/BSS (sound) or other non-GSO/BSS (sound) systems. In view of the fact that the broadcasting-satellite systems employing a type of highly elliptical-orbit for non-GSO/BSS (sound) in the 1-3 GHz band are now being planned for operation in the near future, it would be appropriate to establish coordination procedures applicable to non-GSO/BSS (sound) in respect of GSO/BSS (sound) or other non-GSO/BSS (sound) in the before-mentioned frequency bands with appropriate changes to Article **S5** and Appendix **S5**. Some transitional measures would be necessary to deal with GSO networks filed prior to WRC-2000.

Concerning the frequency sharing between GSO/BSS (sound) and non-GSO/BSS (sound) systems and between non-GSO/BSS (sound) systems in the band 1-3 GHz, the view was expressed that this scope could be included in the provisions of Nos. **S9.12** and **S9.13** or hard limits on non-GSO/BSS (sound) may need to be established to share the frequencies with GSO/BSS (sound).

The same situation could exist with respect to other frequency bands.

7.5.2.10 Possible modifications to Appendix S5

Section 2 of Annex 1 to Appendix **S5** contains "hard limits" which have to be met and which are intended to protect terrestrial services, thereby eliminating the need for coordination between these services and the space stations. For this reason, the CPM proposes to remove Section 2 of that Appendix and to add clarifying language to make it unambiguous that coordination is not required between the space stations and terrestrial services in bands where Article **S21** limits apply. This Section of the Annex is not necessary since the specific power limits are already contained in Articles **S21** and **S22** and these limits are not used to determine the need for coordination.

An example on how these changes could be implemented is provided in the following text. Other editorial changes might be required to Appendix **S5** to correct certain deficiencies as shown in the following examples.

Example change to Table **S5-1** of Appendix **S5**:

TABLE S5-1 *(continued)*

Technical conditions for coordination
(see Article **S9**)

Reference of Article S9	**Case**	**Frequency bands (and Region) of the service for which coordination is sought**	**Threshold/condition**
No. **S9.14** Non-GSO/ terrestrial, GSO/terrestrial	For a space station in a satellite network in the frequency bands for which a footnote refers to No. **S9.11A** in respect of stations of terrestrial services where threshold(s) is (are) exceeded	See Table S5-~~2~~1A	There are no limits in Article **S21** and threshold(s) of~~See~~ § 1 of Annex 1 of this Appendix is(are) exceeded.

One administration expressed its concern about the application of **S9.14** coordination when no trigger is specified in paragraph 1 of Annex 1, and requires a clarification by WRC-2000.

The following are consequential or editorial changes that could be required to AP **S5**~~.~~:

A Example change to Table **S5-1A** of Appendix **S5**:

TABLE S5-1A

Applicability of No. S9.11A for space services

NOTE - Section 1 of Annex 1 contains the relevant coordination thresholds for sharing between the mobile-satellite service (MSS) (space-to-Earth) and terrestrial services. It also contains the relevant coordination thresholds for sharing between non-GSO MSS feeder links (space-to-Earth) and terrestrial services. Section 2 contains the relevant coordination areas for earth stations providing feeder links for non-GSO satellites operating in the MSS and for non-GSO FSS earth stations as well as the relevant coordination areas for mobile earth stations operating below 3 GHz.

B In Table S5-1, **replace** all occurrences of "Table S5-2" to "Table S5-1A" which contains the frequency bands where the relevant Articles apply.

C **Suppress** section 2 of Annex 1, because the limits are already contained in Article **S21** (Sections 2.1, 2.3, 2.4) and **S22** (Section 2.2) and are not used for determining if coordination is required.

D **Renumber** the following sections of Annex 1 and modify §3 of Annex 1 to Appendix **S5** as shown to change the reference from Resolution **46** to Article **S9.11A**.

2 Coordination areas for mobile earth stations operating below 3 GHz and earth stations providing feeder links for non-GSO satellites operating in the MSS and for non-GSO FSS earth stations

2.1 Objectives

In order to apply the provisions of **S9.15** and **S9.16**, this Section specifies the coordination area (see No. **S1.171**) for mobile earth stations as well as earth stations providing feeder links for non-GSO networks. In both cases, the coordination contour (see No. **S1.172**) associated with the coordination area is drawn to scale on an appropriate map in order to depict the coordination area and the extent to which it overlaps the territory of administrations that may be affected. Tables 1-3 specify coordination distances (see No. **S1.173**) for certain frequency sharing situations and frequency bands in which the provisions of Article **S9.11A** are applied. Table 4 applies to non-GSO FSS earth stations.

NOC, remainder of section.

2.2 General considerations

E Update Table 4 of Annex 1 to Appendix **S5** to reflect changes adopted to **S5.523A** at WRC-97.

TABLE 4

Non-GSO FSS earth stations

Frequency sharing situation		**Coordination distance (in sharing situations involving services allocated with equal rights)**
Frequency band and earth station for which coordination area is determined	**Other service or station (station in terrestrial service or earth station)**	
18.~~9~~8-19.3 GHz and 28.~~7~~6-29.1 GHz; earth station operating co-directionally with other earth stations	Ground-based stations in terrestrial services	Determined using Recommendations ITU-R IS.847 and ITU-R IS.849 with the parameters specified therein for terrestrial stations and all applicable equations and figures.

Note – The references in this Table may need to be revised following other decisions by RA-2000 and by WRC-2000.

7.5.3 Resolution 87 - Role of the Notifying Administration

This Resolution deals with the need to clarify the role of the notifying administration when it is notifying on behalf of a group of administrations. There was one administration which submitted proposals and one administration and a Sector Member which submitted comments not in favour of the original proposal. The original proposal which is included here as an example of how WRC-2000 could address this problem would be to have a Resolution with the following *resolves*:

1 that when an administration acts as the notifying administration of a satellite network on behalf of a group of named administrations in accordance with Nos. **S9.1.1** and **S11.15.1** and the Rules of Procedures for Appendices **S30** and **S30A**, the following procedures shall be applied:

- the group of named administrations shall select one of them to act as the notifying administration for that particular network;
- the administration identified as the notifying administration shall act on behalf of all members of the group of administrations listed in the application of the Radio Regulations with respect to particular networks;

2 that the group of named administrations shall ensure that the notifying administration is able to act on their behalf in carrying out the provisions of the Radio Regulations.

There were concerns expressed by one administration and one sector member as follows:

- Some administrations were of the view that the present provisions are adequate, work well and that such changes are not necessary.
- It was pointed out that intergovernmental organizations are composed of sovereign administrations and that the internal procedures of the organization include the identification of the notifying administration to communicate with the BR on its behalf.
- There were concerns expressed about the proposal that the notifying administration shall be one of the group of listed administrations and that the notifying administration may not wish to associate itself with a particular satellite network.

- The view was also expressed that in the case of intergovernmental organizations with its management organization, these organizations are responsible for carrying out the obligations under the Regulations and that the notifying administration is only requested to convey the collective decisions of the intergovernmental organization to the BR and that the notifying administration has no mandate over the intergovernmental organization to enforce the Radio Regulations.
- There were concerns expressed about the conflicting responsibilities between administrations, especially as regards action in the event of harmful interference, when ownership of satellites, licensing of satellites, location of control stations, etc. may involve administrations other than the notifying administration; accordingly the interaction of their relationships, especially the roles of licensing under Article **S18**, needs to be addressed.
- There were concerns that the present provisions of the Radio Regulations only provide an opportunity for the notifying administration to respond to the BR with respect to its own networks if the notifying administration is one of the listed administrations in the group.

In the contributions to some of the main provisions of the Radio Regulations that relate to the roles and responsibilities of the notifying administration were noted as follows:

- **S4.4** - assignment of frequencies not in conformity with the RR by an administration on the condition of no interference;
- **S8.4** - recording of assignments with a reference to No. **S4.4** only when the administration makes a commitment;
- **S9.3** - no comments within a time period equals no objection by the administration, and administrations shall endeavour to cooperate to resolve any difficulties;
- **S9.4** - the administration shall explore all possible means, etc.;
- **S9.43** - an administration not responding shall be considered as not affected;
- **S9.47-49** - an administration undertakes to not make a claim about harmful interference and to not cause harmful interference;
- **S9.51** - an administration shall act within a specified period;
- **S11.36** - undertaking by the notifying administration to not cause harmful interference;
- **S11.39B** - as per No. **S11.36**;
- **Art. S18.**

As for the question of licensing on Article **S18**, this issue is not applicable to Chapter **SIII** of the Radio Regulations, as there is no mention of licensed stations in this Chapter. Article **S18** is a parallel set of obligations under the Radio Regulations and not related to the provisions of Chapter **SIII**.

In addition some administrations do not license or are not authorized by national legislation to license the space stations for which they are the notifying administration and in the case of space stations operated by intergovernmental organizations, they are not licensed by any administration. Also the application of Article **S18** is limited to private stations.

Except for Article **S18** the other provisions listed in paragraph 1.2 fall into one of two categories:

- Those relating to the coordination of specific earth stations and terrestrial stations or between earth stations and the notification and operation of specific earth stations and in this case, it is the administration on whose territory the earth station is situated that is responsible.

- Those relating to the API, coordination, notification and operations of the space station (with typical earth stations as appropriate) and in this case (for non-intergovernmental operating entities) it is the notifying administration of the space station that is responsible. In the case of intergovernmental operating entities, this is the aspect that is not clear and is being addressed in this section.

Administrations are invited to give further consideration to the questions and the concerns expressed above.

7.5.4 Resolution 88 - Processing Charges for Satellite Networks

This Resolution requests WRC-2000 to consider whether any relevant amendments to the Radio Regulations may be necessary, in light of the Council Decision. Council (99) adopted Decision 482. The SC received one contribution on this matter suggesting action by WRC-2000 to deal with the consequences of non-payment of these processing charges. It was suggested that the consequence of non-payment should be addressed in the Radio Regulations, as there are no other provisions of the ITU including the Constitution and the Convention that would apply to this situation. The document suggested that the provisions of the RR should be changed to instruct the Bureau to cancel the relevant publications in the case of non-payment in accordance with the Council Decision. An example of such a change to the Radio Regulations would be footnotes to the appropriate provisions referring to the publications of the Special Sections and is given below.

Add a footnote to that part of Nos. **S9.2B** and **S9.38** referring to the publication, as well as the appropriate provisions of Appendices **S30** and **S30A**.

> If the payments are not received, after suitable reminders, in accordance with the provisions of [Council Decision 482]/[the prevailing Decision of Council] on the Implementation of Cost Recovery for Satellite Network Filings, the Bureau shall cancel the publication and inform all administrations of such action and that this network no longer has to be taken into consideration by other administrations

Some administrations expressed the view that this particular example may not be suitable and that it may impinge upon the rights of administrations under the Radio Regulations, Constitution and the Convention as reflected in the footnote to the Council Decision. Other views were expressed that it is necessary that the administrative process provide for adequate reminders before the BR takes such action. It is to be noted that in signing the Final Acts of a WRC, administrations have certain rights as well as obligations and there are many cases in which administrations' rights are affected in a similar manner in that the right to keep specific satellite filings/frequencies active with ITU are subject to certain conditions such as:

- No. **S9.5D** in which the API publication is cancelled by the Bureau if the coordination request is not received within 24 months of the date of receipt of the API request;
- No. **S11.44** in which the assignments are cancelled by the Bureau if they are not brought into use within the time period provided for by the Regulations;
- Resolution **49** *resolves* 6 in which the publications are cancelled if certain specified data is not provided to ITU within the time period specified.

In addition, Council Decision 482 in *decides* 3 specifically addresses the question of the rights of administrations in that each administration is permitted to have one satellite filing per year at no charge.

****

7.6 Application of RR No. S5.488

7.6.1 Background

A procedural matter related to clarification of provision No. **S5.488** (formerly No. **839**) was brought to the attention of the CPM. This matter was addressed in a document from BR, in an information paper from the Chairman of ITU-R Study Group 9 and in contributions from two administrations.

7.6.2 Summary of regulatory situation

Former Radio Regulations provision RR **839** included the requirement for agreement under Article 14 for FSS in the frequency band 11.7-12.2 GHz in Region 2. This provision was modified by WRC-95 to become **S5.488.** WRC-97 did not introduce any change to that provision.

The RRB revised the Rules of Procedure relating to **S5.488** at its 13th meeting 6-14 July, Geneva, 1998 which became effective as from 1 January 1999. This revision was based on the understanding that the new wording of **S5.488**, with no explicit reference to **S9.21**, means that there is no longer a need for the specific procedures of **S9.21** to be applied to FSS networks in the band 11.7-12.2 GHz in Region 2. The use of the frequency band 11.7-12.2 GHz, for FSS GSO in Region 2, was subject to the application of Article 14 until 1 January 1999.

Since there are now no hard pfd limits applicable to geostationary FSS in this band, the revised Rule removes the only regulatory mechanism available to terrestrial services for their protection from GSO FSS service. It is worth mentioning that terrestrial services are protected from non-GSO FSS systems through provisional pfd levels contained in Resolution **131 (WRC-97)**, and in **S21.16**. All other intra- and inter-service relations in this band are not affected by the modified Rule since, for them, there are other regulatory mechanisms that apply.

In order to bridge the apparent regulatory gap, there is a need to establish an appropriate regulatory mechanism by which the terrestrial service sharing the same frequency band with the space service, on an equal basis, are to be adequately protected.

CPM supported the need to clarify this regulatory procedural situation to ensure protection of the fixed service operating in the band 11.7-12.2 GHz.

7.6.3 Regulatory and procedural considerations

Three approaches were identified:

7.6.3.1 **Approach 1:** The introduction of hard pfd limits for geostationary fixed-satellite networks of Region 2 similar to those currently in Article **S21** (**S21.16**) for non-GSO FSS systems operating in this frequency band. An example of this approach is given in Annex 6 to Chapter 7. Additionally, CPM noted existing Recommendation ITU-R SF.385-5 which identifies maximum permissible values of pfd in the frequency bands above 1 GHz for frequency bands immediately adjacent to the 11.7-12.2 GHz band; these values of pfd, if applied to this frequency band, could constitute hard limits for the use of this band by geostationary FSS of Region 2. Hard limits might be placed in Article **S21**. Also, there may be a need for consequential modifications to **S5.488**.

7.6.3.2 **Approach 2:** The introduction of pfd values which are thresholds. Under this approach, for any Region 2 FSS network exceeding the specified pfd values, there would be a requirement to reach agreement with any affected administration. If WRC-2000 were to decide to adopt trigger values, they might be placed in a new resolution, with consequential modifications to **S5.488**, as given by example in Annex 7 to Chapter 7. Annex 8 to Chapter 7 contains an extract of Recommendation ITU-R SF.674-1 which was used to identify pfd thresholds to facilitate the application of former Article 14 in the identification of potentially-affected administrations. It was noted that these threshold values are 2 dB more stringent than the example hard limits of Annex 6 to Chapter 7.

7.6.3.3 **Approach 3:** Existing provision **S5.488** might be modified to refer explicitly to **S9.21** as shown in Annex 9 to Chapter 7. This example is intended to restore the previous requirement of FSS networks of Region 2 to obtain agreement under former Article 14 (now **S9.21**). Coordination requests under Article 14 now pending in BR are being processed using the pfd values of Recommendation ITU-R SF.674-1 as thresholds to determine affected administrations in regard to the protection of terrestrial services. These values are identical to those given in Annex 7 to Chapter 7. A view was expressed that the reinsertion of **S9.21** does not provide any advantage beyond that of the two previous approaches and has the drawback of implementing a limited period for comments in the regulatory process with potential loss of rights. Consequently, only two ways to protect terrestrial services should be considered - through hard limits (Approach 1) or through coordination thresholds (Approach 2).

ANNEX 1 TO CHAPTER 7

Predetermined coordination distances

(Example of combination and revision of Tables 1 and 2 of Annex 1 of Appendix **S5**)

The predetermined coordination distances specified in Tables 1 and 2 are used for transmitting and receiving earth stations, respectively, in cases defined by the corresponding frequency sharing situation.

TABLE 1

Frequency sharing situation		**Coordination distance** (in sharing situations involving services allocated with equal rights) (km)	***Source of information and comments*** *This column is for clarification purpose only and is not to be kept in the final text that may be included in Appendix* ***S7***
Earth station for which coordination area is determined	**Station in Terrestrial service**		
Ground-based	Mobile (aircraft)	500	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix* ***S5****) for frequencies below 3 GHz No coordination distance is provided for frequencies above 3 GHz (e.g. in the band 5 725-7 075 MHz)*
Aircraft (mobile)	Ground-based	500	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix* ***S5****) for frequencies below 3 GHz Table S5-1 of Appendix* ***S5*** *(under the No.* ***S9.17****) for frequencies above 1 GHz*
Aircraft (mobile)	Mobile (aircraft)	1 000	
Ground-based in the bands: 400.15-401 MHz 1 675-1 700 MHz	Station in the meteorological aids service (radiosonde)	580	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix* ***S5****)*

Aircraft (mobile) in the bands: 400.15-401 MHz 1 675-1 700 MHz	Station in the meteorological aids service (radiosonde)	1 080	
~~Ground-based in the bands:~~ ~~454-456 MHz~~ ~~459-460 MHz~~	~~Ground-based~~	~~500~~	*Table 1 (Section 3 of Annex 1 of Appendix **S5**)* *This case can be deleted since under **S5.286B** MSS earth stations shall not cause harmful interference to, or claim protection from, stations of the fixed or mobile services*
Ground-based in the radiodetermination-satellite service (RDSS) in the bands: 1 610-1 626.5 MHz 2 483.5-2 500 MHz 2 500-2 516.5 MHz	Ground-based	100	*Table S5-1 of Appendix **S5** (under the No. **S9.17**)*
Airborne earth station in the radiodetermination-satellite service (RDSS) in the bands: 1 610-1 626.5 MHz 2 483.5-2 500 MHz 2 500-2 516.5 MHz	Ground-based	400	

Receiving earth stations in the meteorological-satellite service	Station in the meteorological aids service	The coordination distance is considered to be the visibility distance as a function of the earth station horizon elevation angle for a radiosonde at an altitude of 20 km above mean sea level, assuming 4/3 Earth radius (see NOTE 1)	*Table S5-1 of Appendix **S5** (under the No. **S9.17**)* *Note 3 of Recommendation ITU-R IS.850*

TABLE 2

Non-GSO MSS feeder-link earth stations

Frequency sharing situation		**Coordination distance** **(in sharing situations involving services allocated with equal rights) (km)**	***Source of information and comments*** *This column is for clarification purpose only and is not to be kept in the final text that may be included in Appendix **S7***
Earth station for which coordination area is determined	**Other service or station (station in terrestrial service or earth station)**		
Earth station operating in opposite direction in bands in which the FSS is already allocated	Ground-based stations in terrestrial services or Earth station operating in opposite direction of transmission	– 170 (in the band 19.3-19.7 GHz) – 300 (in the band 6 700-7 075 MHz)	*Table 3 (Section 3 of Annex 1 of Appendix **S5**)* *These distances would be in conflict with the ones calculated by using the method provided in the TG 1/6 DNR that may be used for revising Appendix **S7***

Transmit non-GSO MSS feeder-link earth station in the band 15.4-15.7 GHz	Aeronautical radionavigation	"the coordination distances required to protect the aeronautical radionavigation stations from harmful interference from feeder-link earth station emissions are: – 515 km from the aircraft landing surface for aircraft landing systems (ALS) – 600 km from aircraft using general purpose radars (MPR) – 270 km from the aircraft landing for radar sensing and measurement systems"	***S5.511C*** *Recommendation ITU-R S.1340 (recommends 7)* *If these distances have to be counted from the location of the earth station (as defined in **S1.173**) only the worst distance of 600 km is proposed to be retained in order to cover all cases of sharing (e.g. all systems used in aeronautical radionavigation stations). If these distances have to be counted from the terrestrial station, they are not "coordination distances" in the sense of the Radio Regulations and they might not be included in this table but only be referred in Article **S5** as another coordination method*
Receive non-GSO MSS feeder-link earth station in the band 15.4-15.7 GHz	Aeronautical radionavigation	"the threshold distance for the coordination of emissions from stations in the aeronautical radionavigation service with respect to feeder-link earth stations for the MSS based on an earth station antenna gain in the local horizontal plane of 11.5 dBi are: – 150 km from the ground segment for aircraft landing system (ALS) – 600 km from aircraft using general purpose radars – 60 km from the aircraft landing surface for radar sensing and measurement systems"	***S5.511A*** *Recommendation ITU-R S.1341 (recommends 5)* *If these distances have to be counted from the location of the earth station (as defined in **S1.173**) only the worst distance of 600 km is proposed to be retained in order to cover all cases of sharing (e.g. all systems used in aeronautical radionavigation stations). If these distances have to be counted from the terrestrial station, they are not "coordination distances" in the sense of the Radio Regulations and they might not be included in this table but only be referred in Article **S5** as another coordination method*
All bands and earth stations	Terrestrial mobile (aircraft)	500	*Table 3 (Section 3 of Annex 1 of Appendix **S5**)*

NOTE 1 - The coordination distance, d (km), for fixed earth stations in the meteorological-satellite service vis-à-vis stations in the meteorological aids service assumes a radiosonde altitude of 20 km and is determined as a function of the physical horizon elevation angle θ (degrees) for each azimuth, as follows:

$$d = 100 \qquad \textit{for } \theta \geq 11$$

$$d = 582\left(\sqrt{1+(0.254\theta)^2} - 0.254\theta\right) \qquad \textit{for } 0 < \theta < 11,$$

$$d = 582 \qquad \textit{for } \theta \leq 0$$

The minimum and maximum coordination distances are 100 km and 582 km, and correspond with physical horizon angles greater than 11° and less than 0°.

ANNEX 2 TO CHAPTER 7

WRC procedures for adoption of texts for incorporation by reference

According to **CV462** (PP-98: **RoP112**), the texts forming the "Final Acts" are only considered final following approval upon second reading in Plenary. However the texts of Recommendations incorporated by reference will not form part of the Final Acts (see Annex 1 to Resolution **27**) and are therefore not subject to this obligation.

The question then arises of how such texts will actually be approved and accorded treaty status during a WRC. There was a huge potential problem at WRC-97 where the texts identified for incorporation by reference totalled more than 1 000 pages per language. Distributing this material either as input documents or with the Final Acts would have absorbed the entire conference reproduction facilities for five days. This was not acceptable from a logistical point of view but the problem still remained that the principle set out in **CV374** (PP-98: **RoP36**) provides that proposals presented after the opening of the conference shall be published and distributed as conference documents.

However, **CV378** (PP-98: **RoP40**) mitigates this principle inasmuch as it gives the Chairman of the conference or of the relevant committee or working group the discretion to decide whether a proposal submitted during a meeting should or should not be published and distributed as a conference document. WRC-97 therefore proceeded on a similar basis in respect of the texts incorporated by reference. The logic of not reproducing these texts in the Final Acts is reinforced by the fact that WRCs have no mandate to amend such texts; they can only adopt the text or one or more parts thereof as found.

In order for a WRC to incorporate new texts or to update references to texts already incorporated, the following working procedures therefore need to be observed:

– the actual references to Recommendations liable to be incorporated must be published as conference documents, and approved on second reading by the plenary meeting in all cases where a WRC wishes them to be definitively incorporated by reference;

– for a plenary meeting to adopt a text as being definitively incorporated by reference, it is necessary and sufficient that the delegations participating in the plenary meeting should have been provided access to the text in question, but this does not necessarily mean that the texts should be published as official conference documents.

During the course of a WRC it will therefore be necessary to ensure that a list of the Recommendations proposed for incorporation by reference is developed, maintained and published in line with developments during the conference, and that all the listed texts are available for delegates to consult in their final English, Spanish and French versions.

By adoption of a reference to a Recommendation at second reading in accordance with the above conditions, the plenary meeting is therefore deemed to have formally adopted the text of the Recommendation.

ANNEX 3 TO CHAPTER 7

List of ITU-R Recommendations and provisions of the Radio Regulations potentially involved in by incorporation by reference showing suggested priority of work under Resolution 27

Priority (P)	Type of reference and recommended action
A	The reference to an ITU-R Recommendation in this provision is of a **mandatory** character and the referenced text is **explicitly** identified. **Ensure that a standard method of reference is used.**
B	The reference to an ITU-R Recommendation in this provision seems to be of a **mandatory** character and the referenced text is **explicitly** identified, but a **non-standard wording** is used in this respect. There is a **need to review** these provisions with a view to using a standard wording.
C	The reference to an ITU-R Recommendation in this provision is of an **undefined** character, but the referenced text is **explicitly** identified. There is a **need to review** these provisions with a view to indicating the character of the referenced text (i.e. mandatory or non-mandatory).
D	The reference to an ITU-R Recommendation in this provision is of a **non-mandatory** character, but the referenced text is **explicitly** identified. **No need for review**, unless administrations wish to consider changing the character of this provision.

ANNEX 4 TO CHAPTER 7

One possible approach to improving incorporation by reference

1 Introduction

Although the principle of Incorporation by Reference was widely supported by ITU members, its implementation in practice leads to various difficulties; these again lead to lengthy discussions during world radio conferences.

Two reasons may be identified which lead to this situation:

a) In selecting the relevant ITU-R Recommendation, one may be inclined to overlook the fact that the concerned Recommendation was not developed with the clear objective that it should, at a later date, be incorporated into the Radio Regulations; therefore such a Recommendation may contain technical material for which there is not an absolute need to be adopted as part of the Radio Regulations; furthermore, it may be relevant that ITU members are less critical to the context of a document when its purpose remains limited to a recommendation, as compared to a regulatory text.

b) Not the full membership of ITU is in a position to participate actively in the work of the study groups of ITU-R. This means that a large number of ITU members did or could not contribute to the contents of the specific Recommendation, which, only after its adoption, becomes a nominee for a regulatory provision, and therefore gains considerably in importance.

In summary, one might say: the regulatory text was drafted before one knew that it should be a regulatory text.

To overcome these difficulties, ITU should develop procedures which allow the development of the necessary technical provisions in such a way that all ITU members are aware of the fact that at a later stage, the concerned text may have a regulatory character.

2 Example of a selective approach

Therefore, it is proposed that ITU considers the following procedure:

At WRCs decisions should be taken on which subjects the principle of Incorporation by Reference might be applied.

Such could be done via the adoption of a relevant footnote in the Radio Regulations stating that the provisions of Recommendation ITU-R XX-RR-yy to be developed shall apply, from the date of adoption by the next competent WRC.

(XX stands for the character/study group of the Recommendation; RR indicates it is foreseen for Incorporation by Reference, and yy is a serial number.)

In combination with the decision on the footnote, a WRC Resolution may be adopted containing the following basic elements:

a) an instruction to the ITU-R to develop such a Recommendation ITU-R XX-RR-yy;

b) a scope statement for the Recommendation concerned;

c) if desired or appropriate, an annex which contains any pertinent information.

This approach would have the following advantages:

a) it is known in advance that the Recommendation under development will have a regulatory character;

b) the Recommendation will, via the scope statement, limit itself to those requirements which are deemed necessary by the ITU membership;

c) the whole membership of ITU will be aware of the fact that such a text is under development, especially since it carries the special indicator "RR", and will therefore be in a better position to give it the necessary attention during its phase of development and approval in accordance with Resolution ITU-R 1.

This approach would have the following disadvantages:

a) it could result in the adoption of numerous footnotes to the Radio Regulations that have no regulatory impact;

b) it could expand the number of items that have to be automatically considered at future conferences.

ANNEX 5 TO CHAPTER 7

List of ITU-R Recommendations incorporated by reference and the referring provisions of the Radio Regulations

1 Definition of categories

Annex 3 of Resolution **27 (Rev.WRC-97)** identified several categories of provisions making reference to ITU-R Recommendations, notably:

a) The reference to an ITU-R Recommendation is of a **mandatory** character and the referenced text is **explicitly** identified; in such a case, there is a need to **ensure that a standard method of reference is used**.

b) The reference to a Recommendation seems to be of a **mandatory** character and the referenced text is **explicitly** identified, but a **non-standard wording** is used; in such a case, there is a **need to review** the reference with a view to using a standard wording.

c) The reference to a Recommendation is of a **mandatory** character, but the referenced text is **not explicitly** identified; in such a case, there is a **need to review** the reference with a view to identifying the referenced text explicitly and ensure that a standard method of reference is used.

d) The reference to a Recommendation is of a **non-mandatory** character, but the referenced text is **explicitly** identified; in such a case there is **no need for review**, unless administrations wish to consider changing the character of the referenced text.

e) The reference to a Recommendation is of a **non-mandatory** character, but the referenced text is **not explicitly** identified; in such a case there is **no need for review**, unless administrations wish to consider changing the character of the referenced text.

f) The reference to a Recommendation is of an **undefined** character, but the referenced text is **explicitly** identified; in such a case, there is a **need to review** the reference with a view to indicating the character of the referenced text (i.e., mandatory or non-mandatory).

g) The reference to a Recommendation is of an **undefined** character, but the referenced text is **not explicitly** identified; in such a case, there is a **need to review** the reference with a view to indicating the character of the referenced text (i.e., mandatory or non-mandatory) and, if necessary, **to identify** the referenced text explicitly.

2 Provisions of category A (see paragraph 1 above)

No.	Text (RR-98)	Possible action
S5.287	In the maritime mobile service, the frequencies 457.525 MHz, 457.550 MHz, 457.575 MHz, 467.525 MHz, 467.550 MHz and 467.575 MHz may be used by on-board communication stations. Where needed, equipment designed for 12.5 kHz channel spacing using also the additional frequencies 457.5375 MHz, 457.5625 MHz, 467.5375 MHz and 467.5625 MHz may be introduced for on-board communications. The use of these frequencies in territorial waters may be subject to the national regulations of the administration concerned. The characteristics of the equipment used shall conform to those specified in Recommendation ITU-R M.1174 (see Resolution **341 (WRC-97)**). (WRC-97)	NOC
S5.288	In the territorial waters of the United States and the Philippines, the preferred frequencies for use by on-board communication stations shall be 457.525 MHz, 457.550 MHz, 457.575 MHz and 457.600 MHz paired, respectively, with 467.750 MHz, 467.775 MHz, 467.800 MHz and 467.825 MHz. The characteristics of the equipment used shall conform to those specified in Recommendation ITU-R M.1174.	NOC
S5.391	In making assignments to the mobile service in the bands 2 025-2 110 MHz and 2 200-2 290 MHz, administrations shall not introduce high-density mobile systems, as described in Recommendation ITU-R SA.1154, and shall take that Recommendation into account for the introduction of any other type of mobile system. (WRC-97)	NOC *Note: Recommendation ITU-R SA.1154 has to be included in any further revision of Annex 4 to Resolution* ***27****, as well as in Volume 4 of the RR.*

S5.511C	Stations operating in the aeronautical radionavigation service shall limit the effective e.i.r.p. in accordance with Recommendation ITU-R S.1340. The minimum coordination distance required to protect the aeronautical radionavigation stations (No. **S4.10** applies) from harmful interference from feeder-link earth stations and the maximum e.i.r.p. transmitted towards the local horizontal plane by a feeder-link earth station shall be in accordance with Recommendation ITU-R S.1340. (WRC-97)	NOC *Note: Recommendation ITU-R S.1340 has to be included in any further revision of Annex 4 to Resolution* ***27****, as well as in Volume 4 of the RR.*
S19.38	§ 19 1) Each administration shall choose the call signs and, if the selective calling system used is in accordance with Recommendation ITU-R M.257-3, the ship station selective call numbers and the coast station identification numbers of its stations from the international series allocated or supplied to it; and shall notify this information to the Secretary-General together with the information which is to appear in Lists I, IV, V, VI and VIIIA. These notifications do not include call signs assigned to amateur and experimental stations.	§ 19 1) Each administration shall choose the call signs and, <u>where appropriate,</u> ~~if the selective calling system used is in accordance with Recommendation ITU-R M.257-3,~~ the ship station selective call numbers and the coast station identification numbers of its stations from the international series allocated or supplied to it; and shall notify this information to the Secretary-General together with the information which is to appear in Lists I, IV, V, VI and VIIIA. These notifications do not include call signs assigned to amateur and experimental stations. *Justification: The emphasis of this provision is on the selection of the means of identities, and not on the technical characteristics. They are dealt with in No.* ***S54.2****.*
S19.48	*b)* [shall not be used as call signs:] combinations reserved for the abbreviations to be used in the radiocommunication services (see Recommendation ITU-R M.1172).	*b)* [shall not be used as call signs:] combinations reserved for the abbreviations to be used in the radiocommunication services<u>, which are in accordance with</u> ~~(see~~ Recommendation ITU-R M.1172~~)~~.
S19.92	§ 38 1) In cases where selective call numbers for ship stations and identification numbers for coast stations are required for use in the maritime mobile service and the selective calling system is in accordance with Recommendation ITU-R M.257-3, the selective call numbers and identification numbers shall be supplied by the Secretary-General on request. Upon notification by an administration of the introduction of selective calling for use in the maritime mobile service:	§ 38 1) In <u>the</u> case where <u>the sequential single frequency</u> selective<u>-calling system is used,</u> ~~call numbers for ship stations and identification numbers for coast stations are required for use in the maritime mobile service and the selective calling system is in accordance with Recommendation ITU-R M.257-3,~~ the selective call numbers and identification numbers shall be supplied by the Secretary-General on request. Upon notification by an administration of the introduction of selective calling for use in the maritime mobile service:

S22.5A	§ 5 In the frequency band 6 700-7 075 MHz, the maximum aggregate power flux-density produced at the geostationary-satellite orbit and within ±5° of inclination around the geostationary-satellite orbit by a non-geostationary-satellite system in the fixed-satellite service shall not exceed –168 dB(W/m^2) in any 4 kHz band. The maximum aggregate power flux-density shall be calculated in accordance with Recommendation ITU-R S.1256. (WRC-97)	NOC *Note: Recommendation ITU-R S.1256 has to be included in any further revision of Annex 4 to Resolution **27**, as well as in Volume 4 of the RR.*
S22.5C	§ 6 1) The equivalent power flux-density[2], at any point on the Earth's surface visible from the geostationary-satellite orbit, produced by emissions from all the space stations of a non-geostationary-satellite system in the fixed-satellite service in the frequency bands listed in Table **S22-1**, including emissions from a reflecting satellite, for all conditions and for all methods of modulation, shall not exceed the limits given in Table **S22-1** for the given percentages of time. These limits relate to the equivalent power flux-density which would be obtained under free-space propagation conditions, into a reference antenna and in the reference bandwidth specified in Table **S22-1**, for all pointing directions towards the geostationary-satellite orbit. (WRC-97)	NOC *Note: Table **S22-1** contains reference to Recommendation ITU-R BO.1213, which is already included in Volume 4 of the RR.*
S47.26	§ 8 1) The holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate is authorized to embark as chief operator of a ship station of the fourth category (see Recommendation ITU-R M.1169).	§ 8 1) The holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate is authorized to embark as chief operator of a ship station of the fourth category, as defined in ~~(see~~ Recommendation ITU-R M.1169~~)~~.

[2] **S22.5C.1** (Not reproduced).

S47.27	2) However, before becoming chief or sole operator of a ship station of the fourth category (see Recommendation ITU-R M.1169) which is required by international agreements to carry a radiotelegraph operator, the holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate shall have had adequate experience as operator on board ship at sea.	2) However, before becoming chief or sole operator of a ship station of the fourth category, as defined in ~~(see~~ Recommendation ITU-R M.1169~~,)~~ which is required by international agreements to carry a radiotelegraph operator, the holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate shall have had adequate experience as operator on board ship at sea.
S47.28	3) Before becoming chief operator of a ship station of the second or third category (see Recommendation ITU-R M.1169), the holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate shall have had, as operator on board ship or in a coast station, at least six months' experience of which at least three months shall have been on board ship.	3) Before becoming chief operator of a ship station of the second or third category, as defined in ~~(see~~ Recommendation ITU-R M.1169~~)~~, the holder of a radiocommunication general operator's certificate or a first- or second-class radiotelegraph operator's certificate shall have had, as operator on board ship or in a coast station, at least six months' experience of which at least three months shall have been on board ship.
S47.29	4) Before becoming chief operator of a ship station of the first category (see Recommendation ITU-R M.1169), the holder of a radiocommunication general operator's certificate or a first-class radiotelegraph operator's certificate shall have had, as operator on board ship or in a coast station, at least one year's experience of which at least six months shall have been on board ship.	4) Before becoming chief operator of a ship station of the first category, as defined in Recommendation ITU-R M.1169, the holder of a radiocommunication general operator's certificate or a first-class radiotelegraph operator's certificate shall have had, as operator on board ship or in a coast station, at least one year's experience of which at least six months shall have been on board ship.
S50.9	§ 5 The services of ship stations for international public correspondence shall be provided in accordance with the provisions of Recommendation ITU-R M.1169.	NOC
S51.35	*b)* send and receive class F1B or J2B emissions on an international calling channel (see Recommendation ITU-R M.541-8) in each of the HF maritime mobile bands necessary for their service;	*b)* send and receive class F1B or J2B emissions on an international calling channel (see Part A of Appendix S17 ~~Recommendation ITU-R M.541-8~~) in each of the HF maritime mobile bands necessary for their service; *Justification: The emphasis in this provision is on the indication of the relevant frequencies, rather than on the detailed procedures.*

S51.41	2) The characteristics of the narrow-band direct-printing equipment shall be in accordance with Recommendations ITU-R M.476-5, ITU-R M.625-3 and ITU-R M.627-1.	NOC
S51.77	*d)* except as provided in No. **S51.75**, aircraft station transmitters shall comply with the technical characteristics given in Recommendation ITU-R M.489-2;	NOC
S52.25	4) Before transmitting on 500 kHz, stations must listen on this frequency for a reasonable period to make sure that no distress traffic is being sent (see Recommendation ITU-R M.1170).	4) Before transmitting on 500 kHz, stations must listen on this frequency for a reasonable period to make sure that no distress traffic is being sent. ~~(see Recommendation ITU-R M.1170).~~ *Justification: The reference to Recommendation ITU-R M.1170 is redundant as it specifies the same condition in a slightly different language.*
S52.27	§ 11 1) The general calling frequency which, except as provided under Recommendation ITU-R M.492-6, shall be used by any ship station or coast station engaged in radiotelegraphy in the authorized bands between 415 kHz and 535 kHz, and by aircraft stations desiring to enter into communication with a station of the maritime mobile service using frequencies in these bands, is the frequency 500 kHz.	§ 11 1) The general calling frequency which~~, except as provided under Recommendation ITU-R M.492-6,~~ shall be used by any ship station or coast station engaged in radiotelegraphy in the authorized bands between 415 kHz and 535 kHz, and by aircraft stations desiring to enter into communication with a station of the maritime mobile service using frequencies in these bands, is the frequency 500 kHz. However, when using direct-printing telegraphy or similar systems in any of these frequency bands allocated to the maritime mobile service, the call may, by prior arrangement, be made on a working frequency available for such systems. *Justification: The broad reference to Recommendation ITU-R M.492-6 does not provide for sufficient guidance.*

S52.31	§ 13 1) The frequency for replying to a call sent on the general calling frequency (see No. **S52.27**) shall be as follows: – either 500 kHz, – or the frequency specified by the calling station (see No. **S52.29** and Recommendation ITU-R M.1170).	§ 13 1) The frequency for replying to a call sent on the general calling frequency (see No. **S52.27**) shall be as follows: – either 500 kHz, – or the frequency on which the calling station keeps watch, unless the ~~specified by the~~ calling station has specified a frequency for the reply (see No. **S52.29** ~~and Recommendation ITU-R M.1170~~). *Justification: The broad reference to Recommendation ITU-R M.1170 does not provide for sufficient guidance.*
S52.69	§ 28 In order to reduce interference on Morse radiotelegraphy calling frequencies, a coast station shall take adequate steps to ensure, under normal conditions, the prompt receipt of Morse radiotelegraphy calls (see Recommendation ITU-R M.1170).	§ 28 In order to reduce interference on Morse radiotelegraphy calling frequencies, a coast station shall take adequate steps to ensure, under normal conditions, the prompt receipt of Morse radiotelegraphy calls in accordance with ~~(see~~ Recommendation ITU-R M.1170~~)~~.
S52.159	§ 71 1) The frequency 156.525 MHz is an international frequency in the maritime mobile service used for distress, urgency, safety and calling by digital selective-calling techniques (see Nos. **S33.8** and **S33.31**, Appendix **S15** and Recommendation ITU-R M.541-8).	§ 71 1) The frequency 156.525 MHz is an international frequency in the maritime mobile service used for distress, urgency, safety and calling by digital selective-calling techniques (see Nos. **S33.8**, ~~and~~ **S33.31** and **S54.2**, as well as Appendix **S15** ~~and Recommendation ITU-R M.541-8~~). *Justification: With the introduction of the reference to **S54.2**, the reference to Recommendation ITU-R M.541-8 becomes redundant.*
S52.181	§ 85 Single-sideband apparatus in radiotelephone stations of the maritime mobile service operating in the bands allocated to this service between 1 605 kHz and 4 000 kHz and in the bands allocated exclusively to this service between 4 000 kHz and 27 500 kHz shall satisfy the technical and operational conditions specified in Recommendation ITU-R M.1173.	NOC

S52.195	§ 89 1) Before transmitting on the carrier frequency 2 182 kHz, a station shall listen on this frequency for a reasonable period to make sure that no distress traffic is being sent (see Recommendation ITU-R M.1171).	§ 89 1) Before transmitting on the carrier frequency 2 182 kHz, a station shall listen on this frequency for a reasonable period to make sure that no distress traffic is being sent~~ (see Recommendation ITU-R M.1171)~~. *Justification: The reference to Recommendation ITU-R M.1171 is superfluous, as it does not contain any additional information in this respect.*
S52.222.1	These frequencies may also be used by coast stations with class H2B emission, when using the selective calling system defined in Recommendation ITU-R M.257-3.	These frequencies may also be used by coast stations with class H2B emission, when using the <u>sequential single-frequency </u>selective calling system~~ defined in Recommendation ITU-R M.257-3~~.
S52.224	§ 99 1) Before transmitting on the carrier frequencies 4 125 kHz, 6 215 kHz, 8 291 kHz, 12 290 kHz or 16 420 kHz a station shall listen on the frequency for a reasonable period to make sure that no distress traffic is being sent (see Recommendation ITU-R M.1171).	§ 99 1) Before transmitting on the carrier frequencies 4 125 kHz, 6 215 kHz, 8 291 kHz, 12 290 kHz or 16 420 kHz a station shall listen on the frequency for a reasonable period to make sure that no distress traffic is being sent~~ (see Recommendation ITU-R M.1171)~~. *Justification: The reference to Recommendation ITU-R M.1171 is superfluous, as it does not contain any additional information in this respect.*
S52.229	4) The technical characteristics of transmitters used for radiotelephony in the bands between 4 000 kHz and 27 500 kHz are specified in Recommendation ITU-R M.1173.	4) The technical characteristics of <u>single-sideband </u>transmitters used for radiotelephony in the bands between 4 000 kHz and 27 500 kHz <u>shall conform to those </u>~~are~~ specified in Recommendation ITU-R M.1173.
S52.231	§ 101 1) The frequency 156.8 MHz is the international frequency for distress traffic and for calling by radiotelephony when using frequencies in the authorized bands between 156 MHz and 174 MHz (see Appendix **S13** for details of use). The class of emission to be used for radiotelephony on the frequency 156.8 MHz shall be G3E (see Recommendation ITU-R M.489-2).	§ 101 1) The frequency 156.8 MHz is the international frequency for distress traffic and for calling by radiotelephony when using frequencies in the authorized bands between 156 MHz and 174 MHz (see Appendix **S13** for details of use). The class of emission to be used for radiotelephony on the frequency 156.8 MHz shall be G3E~~ (see Recommendation ITU-R M.489-2)~~. *Justification: The reference to Recommendation ITU-R M.489-2 is misleading as it specifies the relevant condition in a different manner (e.g., "the class of emission should be F3E/G3E").*

S52.240	8) Before transmitting on the frequency 156.8 MHz, a station shall listen on this frequency for a reasonable period to make sure that no distress traffic is being sent (see Recommendation ITU-R M.1171).	8) Before transmitting on the frequency 156.8 MHz, a station shall listen on this frequency for a reasonable period to make sure that no distress traffic is being sent~~ (see Recommendation ITU-R M.1171)~~. *Justification: The reference to Recommendation ITU-R M.1171 is superfluous, as it does not contain any additional information in this respect.*
S55.1	The radiotelegraph procedure detailed in Recommendation ITU-R M.1170 is obligatory, except in cases of distress, urgency, or safety, to which the provisions of Appendix **S13** are applicable.	NOC
S57.1	§ 1 The procedure detailed in Recommendation ITU-R M.1171 is applicable to radiotelephone stations, except in cases of distress, urgency or safety, to which the provisions of Appendix **S13** are applicable.	NOC

3 Provisions of category B (see paragraph 1 above)

S1.14	*Coordinated Universal Time (UTC):* Time scale, based on the second (SI), as defined in ITU-R Recommendation ITU-R TF.460-5. For most practical purposes associated with the Radio Regulations, UTC is equivalent to mean solar time at the prime meridian (0° longitude), formerly expressed in GMT.	*Coordinated Universal Time (UTC):* Time scale, based on the second (SI), in accordance with the definition ~~as defined~~ in ITU-R Recommendation ITU-R TF.460-5. For most practical purposes associated with the Radio Regulations, UTC is equivalent to mean solar time at the prime meridian (0° longitude), formerly expressed in GMT.

S5.511A	Use of the band 15.43-15.63 GHz by the fixed-satellite service (space-to-Earth (see Resolution **123 (WRC-97)**) and Earth-to-space) is limited to feeder links of non-geostationary systems in the mobile-satellite service, subject to coordination under No. **S9.11A**. In the space-to-Earth direction, the minimum earth station elevation angle above and gain towards the local horizontal plane and the minimum coordination distances to protect an earth station from harmful interference shall be in accordance with Recommendation ITU-R S.1341. Also in the space-to-Earth direction, harmful interference shall not be caused to stations of the radio astronomy service using the band 15.35-15.4 GHz. The threshold levels of interference and associated power flux-density limits which are detrimental to the radio astronomy service are given in Recommendation ITU-R RA.769-1. Special measures will need to be employed to protect the radio astronomy service in the band 15.35-15.4 GHz. (WRC-97)	NOC
S52.23	*b)* by coast stations to announce by means of Morse telegraphy the transmission of their traffic lists under the conditions provided for in Recommendation ITU-R M.1170.	*b)* by coast stations to announce by means of Morse telegraphy the transmission of their traffic lists to all stations, in accordance with ~~under the conditions provided for in~~ Recommendation ITU-R M.1170.
S52.235	3) The frequency 156.8 MHz may be used by ship stations and coast stations for selective calling as defined in Recommendation ITU-R M.257-3.	3) The frequency 156.8 MHz may be used by ship stations and coast stations for selective calling using the sequential single frequency calling system.~~as defined in Recommendation ITU-R M.257-3.~~

4 Provisions of category C (see paragraph 1 above)

S3.2	Also, as far as is compatible with practical considerations, the choice of transmitting, receiving and measuring equipment shall be based on the most recent advances in the technique as indicated, *inter alia*, in ITU-R Recommendations.	Also, as far as is compatible with practical considerations, the choice of transmitting, receiving and measuring equipment should ~~shall~~ be based on the most recent advances in the technique as indicated, *inter alia*, in ITU-R Recommendations. *Justification: The combination "as far as..." and "shall" is inherently inconsistent.*
S5.138	The following bands: 6 765-6 795 kHz (centre frequency 6 780 kHz), 433.05-434.79 MHz (centre frequency 433.92 MHz) in Region 1 except in the countries mentioned in No. **S5.280**, 61-61.5 GHz (centre frequency 61.25 GHz), 122-123 GHz (centre frequency 122.5 GHz), and 244-246 GHz (centre frequency 245 GHz) are designated for industrial, scientific and medical (ISM) applications. The use of these frequency bands for ISM applications shall be subject to special authorization by the administration concerned, in agreement with other administrations whose radiocommunication services might be affected. In applying this provision, administrations shall have due regard to the latest relevant ITU-R Recommendations.	The following bands: 6 765-6 795 kHz (centre frequency 6 780 kHz), 433.05-434.79 MHz (centre frequency 433.92 MHz) in Region 1 except in the countries mentioned in No. **S5.280**, 61-61.5 GHz (centre frequency 61.25 GHz), 122-123 GHz (centre frequency 122.5 GHz), and 244-246 GHz (centre frequency 245 GHz) are designated for industrial, scientific and medical (ISM) applications. The use of these frequency bands for ISM applications shall be subject to special authorization by the administration concerned, in agreement with other administrations whose radiocommunication services might be affected. ~~In applying this provision, administrations shall have due regard to the latest relevant ITU-R Recommendations.~~ *Justification: The deleted phrase has no regulatory implications as it does not indicate any specific Recommendation.*

S5.458C	Administrations making submissions in the band 7 025-7 075 MHz (Earth-to-space) for geostationary-satellite systems in the fixed-satellite service after 17 November 1995 shall consult on the basis of relevant ITU-R Recommendations with the administrations that have notified and brought into use non-geostationary-satellite systems in this frequency band before 18 November 1995 upon request of the latter administrations. This consultation shall be with a view to facilitating shared operation of both geostationary-satellite systems in the fixed-satellite service and non-geostationary-satellite systems in this band.	Administrations making submissions in the band 7 025-7 075 MHz (Earth-to-space) for geostationary-satellite systems in the fixed-satellite service after 17 November 1995 shall consult ~~on the basis of relevant ITU-R Recommendations~~ with the administrations that have notified and brought into use non-geostationary-satellite systems in this frequency band before 18 November 1995 upon request of the latter administrations. This consultation shall be with a view to facilitating shared operation of both geostationary-satellite systems in the fixed-satellite service and non-geostationary-satellite systems in this band. *Justification: The emphasis in this provision is on consultation. It is obvious that the administrations will use the relevant ITU-R Recommendations in such consultations.*
S13.13	The Rules of Procedure shall include, inter alia, calculation methods and other data required for the application of these Regulations. These shall be based upon the decisions of world radiocommunication conferences and the Recommendations of the Radiocommunication Sector. Where requirements arise for new data for which there are no such decisions or Recommendations the Bureau shall develop such data in accordance with No. **S13.14**, and shall revise them when appropriate decisions or Recommendations are available.	NOC
S21.1	§ 1 Sites and frequencies for terrestrial stations and earth stations, operating in frequency bands shared with equal rights between terrestrial radiocommunication and space radiocommunication services, shall be selected having regard to the relevant ITU-R Recommendations with respect to geographical separation between earth stations and terrestrial stations.	§ 1 Sites and frequencies for terrestrial stations and earth stations, operating in frequency bands shared with equal rights between terrestrial radiocommunication and space radiocommunication services, <u>should</u> ~~shall~~ be selected having regard to the relevant ITU-R Recommendations with respect to geographical separation between earth stations and terrestrial stations. *Justification: The linking mandatory language ("shall") is inoperative in view of the lack of explicit references.*

S29.13	§ 10 Administrations shall take note of the relevant ITU-R Recommendations with the aim of limiting interference to the radio astronomy service from other services.	§ 10 Administrations are urged to ~~shall~~ take note of the relevant ITU-R Recommendations with the aim of limiting interference to the radio astronomy service from other services.
S32.5	§ 4 Digital selective calling shall be in accordance with the relevant ITU-R Recommendations.	SUP *Justification: This provision is redundant, as No.* ***S54.2*** *contains the necessary information in a clear and explicit manner.*
S32.9.3	The format of distress calls and distress messages shall be in accordance with the relevant ITU-R Recommendations (see Resolution **27 (Rev.WRC-97)**).	The format of distress calls and distress messages shall be in accordance with the relevant ITU-R Recommendations (see Resolution **27 (Rev.WRC-97)**). *Note: The linking mandatory language ("shall") is inoperative in view of the lack of explicit references. The relevant ITU-R Recommendations are M.493-9 (for DSC), M.632-3 (for satellite EPIRBs in the 1.6 GHz band) and M.633-1 (for satellite EPIRBs in the 406 MHz band).*
S32.21	§ 13 Acknowledgement by digital selective calling of receipt of a distress alert in the terrestrial services shall be in accordance with relevant ITU-R Recommendations (see Resolution **27 (Rev.WRC-97)**).	SUP *Justification: This provision is redundant, as No.* ***S54.2*** *contains the necessary information in a clear and explicit manner.*
S32.43	§ 27 1) Error correction techniques in accordance with relevant ITU-R Recommendations shall be used for distress traffic by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the distress signal MAYDAY.	§ 27 1) Error correction techniques ~~in accordance with relevant ITU-R Recommendations~~ shall be used for distress traffic by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the distress signal MAYDAY. *Justification: The reference to ITU-R Recommendations in this provision is redundant as No.* ***S51.41*** *contains the necessary information in a clear and explicit manner (mandatory incorporation by reference).*

S32.64	4) Locating signals shall be in accordance with the relevant ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	SUP *Justification: The linking mandatory language ("shall") is inoperative in view of the lack of explicit references.*
S33.17	§ 9 1) Error correction techniques in accordance with relevant ITU-R Recommendations shall be used for urgency messages by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the urgency signal PAN PAN.	§ 9 1) Error correction techniques ~~in accordance with relevant ITU-R Recommendations~~ shall be used for urgency messages by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the urgency signal PAN PAN. *Justification: The reference to ITU-R Recommendations in this provision is redundant as No.* ***S51.41*** *contains the necessary information in a clear and explicit manner (mandatory incorporation by reference).*
S33.37	§ 20 1) Error correction techniques in accordance with relevant ITU-R Recommendations shall be used for safety messages by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the safety signal SECURITE.	§ 20 1) Error correction techniques ~~in accordance with relevant ITU-R Recommendations~~ shall be used for safety messages by direct-printing telegraphy. All messages shall be preceded by at least one carriage return, a line feed signal, a letter shift signal and the safety signal SECURITE. *Justification: The reference to ITU-R Recommendations in this provision is redundant as No.* ***S51.41*** *contains the necessary information in a clear and explicit manner (mandatory incorporation by reference).*
S33.41	§ 22 The mode and format of the transmissions mentioned in Nos. **S33.43**, **S33.45**, **S33.46** and **S33.48** shall be in accordance with the relevant ITU-R Recommendations.	SUP *Justification: The linking mandatory language ("shall") is inoperative in view of the lack of explicit references. This provision is redundant as No.* ***S51.41*** *contains the necessary information in a clear and explicit manner (mandatory incorporation by reference).*
S34.1	§ 1 The emergency position-indicating radiobeacon signal transmitted on 156.525 MHz and satellite EPIRB signals in the band 406-406.1 MHz or 1 645.5-1 646.5 MHz shall be in accordance with relevant ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	SUP *Justification: The linking mandatory language ("shall") is inoperative in view of the lack of explicit references.*

S34.2	§ 2 The characteristics of the "distress call" (see No. **S32.9**) in the digital selective calling system shall be in accordance with relevant ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	SUP *Justification: This provision is redundant, as No.* ***S54.2*** *contains the necessary information in a clear and explicit manner.*
S51.25	§ 12 The characteristics of the digital selective calling equipment shall be in accordance with ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	SUP *Justification: This provision is redundant, as No.* ***S54.2*** *contains the necessary information in a clear and explicit manner.*
S52.112	§ 51 The characteristics of the digital selective-calling equipment shall be in accordance with the relevant ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	SUP *Justification: This provision is redundant, as No.* ***S54.2*** *contains the necessary information in a clear and explicit manner.*
S58.1	The provisions of the International Telecommunications Regulations, taking into account ITU-T Recommendations, shall apply.	NOC

5 Provisions of category D (see paragraph 1 above)

S5.208A	In making assignments to space stations in the mobile-satellite service in the bands 137-138 MHz, 387-390 MHz and 400.15-401 MHz, administrations shall take all practicable steps to protect the radio astronomy service in the bands 150.05-153 MHz, 322-328.6 MHz, 406.1-410 MHz and 608-614 MHz from harmful interference from unwanted emissions. The threshold levels of interference detrimental to the radio astronomy service are shown in Table 1 of Recommendation ITU-R RA.769-1. (WRC-97)	NOC

S5.503A	Until 1 January 2000, stations in the fixed-satellite service shall not cause harmful interference to non-geostationary space stations in the space research and Earth exploration-satellite services. After that date, these non-geostationary space stations will operate on a secondary basis in relation to the fixed-satellite service. Additionally, when planning earth stations in the fixed-satellite service to be brought into service between 1 January 2000 and 1 January 2001, in order to accommodate the needs of spaceborne precipitation radars operating in the band 13.793-13.805 GHz, advantage should be taken of the consultation process and the information given in Recommendation ITU-R SA.1071.	NOC
S5.536A	Administrations installing earth exploration-satellite earth stations cannot claim protection from fixed and mobile stations operated by neighbouring administrations. In addition, earth stations operating in the earth exploration-satellite service should take into account Recommendation ITU-R SA.1278. (WRC-97)	NOC *Note: Recommendation ITU-R SA.1278 has to be included in any further revision of Annex 4 to Resolution **27**, but not in Volume 4 of the RR.*
S16.6	Administrative and procedural requirements for use and operation of the international monitoring system should be in accordance with the provisions of Recommendation ITU-R SM.1139.	NOC
S21.2.2 **S21.4.1**	Information on this subject is given in the most recent version of Recommendation ITU-R SF.765 (see Resolution **27 (Rev.WRC-97)**).	<u>For calculation of the separation angles between radio-relay antenna beams and the geostationary-satellite orbits, administrations may use</u> ~~Information on this subject is given in~~ the most recent version of Recommendation ITU-R SF.765 ~~(see Resolution 27 (Rev.WRC-97))~~.
S29.12	§ 9 In applying the measures outlined in this Section, administrations are urged to bear in mind that the radio astronomy service is extremely susceptible to interference from space and airborne transmitters (for further information, see Recommendation ITU-R RA.769).	NOC
S32.7	§ 6 The Phonetic Alphabet and Figure Code in Appendix **S14** and the abbreviations and signals in accordance with Recommendation ITU-R M.1172 should be used where applicable[1].	NOC

S51.71	§ 28 In the case of communication between stations on board aircraft and stations of the maritime mobile service, radiotelephone calling may be renewed as specified in Recommendation ITU-R M.1171 and radiotelegraph calling may be renewed after an interval of five minutes, notwithstanding Recommendation ITU-R M.1170.	§ 28 In the case of communication between stations on board aircraft and stations of the maritime mobile service, radiotelephone calling may be renewed ~~as specified in Recommendation ITU-R M.1171~~ under the following conditions: 1) when a station called does not reply to a call sent three times at intervals of two minutes, the calling shall cease; 2) however, when a station called does not reply, the call may be repeated at three minute intervals. § 28A In the case of communication between stations on board aircraft and stations of the maritime mobile service, ~~and~~ radiotelegraph calling may be renewed after an interval of five minutes.~~, notwithstanding Recommendation ITU-R M.1170.~~ *Justification: Provision Nos.* ***S55.1*** *and* ***S57.1*** *make a clear and explicit reference to the mandatory character of the procedures referred to in Recommendations ITU-R M.1170 and ITU-R M.1171. The current linking provision in No.* ***S51.71*** *("may") gives the impression of a non-mandatory character, although the procedures of Recommendation ITU-R M.1170 are mandatory.*
S52.32	2) In regions of heavy traffic, coast stations may answer calls made by ship stations of their own nationality in accordance with special arrangements made by the administration concerned (see Recommendation ITU-R M.1170).	2) In regions of heavy traffic, coast stations may answer calls made by ship stations of their own nationality in accordance with special arrangements made by the administration concerned ~~(see Recommendation ITU-R M.1170)~~. *Justification: The emphasis in this provision is on the national arrangements. The reference to Recommendation ITU-R M.1170 is superfluous as provision No.* ***S55.1*** *makes a clear and explicit reference to the mandatory character of the procedures referred to in Recommendation ITU-R M.1170.*

S52.63	2) So far as is practicable, a coast station shall transmit its calls at specified times in the form of traffic lists on the frequency or frequencies indicated in the List of Coast Stations (see Recommendation ITU-R M.1170).	2) So far as is practicable, a coast station shall transmit its calls at specified times in the form of traffic lists on the frequency or frequencies indicated in the List of Coast Stations~~ (see Recommendation ITU-R M.1170)~~. *Justification: The reference to Recommendation ITU-R M.1170 is superfluous as provision No.* ***S55.1*** *makes a clear and explicit reference to the mandatory character of the procedures referred to in Recommendation ITU-R M.1170.*
S52.148	*b)* subject to the provisions of No. **S52.149**, one of the international digital selective-calling frequencies indicated in Recommendation ITU-R M.541-8.	*b)* subject to the provisions of No. **S52.149**, one of the international digital selective-calling frequencies indicated in Part A of Appendix **S17**. ~~Recommendation ITU-R M.541-8.~~
S52.152	*b)* subject to the provisions of No. **S52.153**, one of the international digital selective-calling frequencies indicated in Recommendation ITU-R M.541-8.	*b)* subject to the provisions of No. **S52.153**, one of the international digital selective-calling frequencies indicated in Part A of Appendix **S17**. ~~Recommendation ITU-R M.541-8.~~
S52.153	2) The international digital selective-calling frequencies indicated in Recommendation ITU-R M.541-8 may be assigned to any coast station. In order to reduce interference on these frequencies, they may be used as a general rule by coast stations to call ships of another nationality, or in cases where it is not known on which digital selective-calling frequencies within the bands concerned the ship station is maintaining watch.	2) The international digital selective-calling frequencies indicated in Part A of Appendix **S17** ~~Recommendation ITU-R M.541-8~~ may be assigned to any coast station. In order to reduce interference on these frequencies, they may be used as a general rule by coast stations to call ships of another nationality, or in cases where it is not known on which digital selective-calling frequencies within the bands concerned the ship station is maintaining watch.
S52.234	*b)* by coast stations to announce the transmission on another frequency of traffic lists and important maritime information (see Recommendation ITU-R M.1171).	*b)* by coast stations to announce the transmission on another frequency of traffic lists and important maritime information~~ (see Recommendation ITU-R M.1171)~~. *Justification: The broad reference to Recommendation ITU-R M.1171 does not serve any useful purpose. In any case, Recommendation ITU-R M.1171 is of a mandatory character, as specified in No.* ***S57.1***.

S54.2	2) Selective calling may be carried out using a sequential single-frequency code system in accordance with Recommendation ITU-R M.257-3 or a digital selective-calling system in accordance with Recommendations ITU-R M.493-9, ITU-R M.541-8, ITU-R M.821-1 and ITU-R M.825-2 in the shore-to-ship, ship-to-shore and ship-to-ship directions.	2) Selective calling shall ~~may~~ be carried out using either a sequential single-frequency code system in accordance with Recommendation ITU-R M.257-3 or a digital selective-calling system in accordance with Recommendations ITU-R M.493-9, ITU-R M.541-8, ITU-R M.821-1 and ITU-R M.825-2 in the shore-to-ship, ship-to-shore and ship-to-ship directions. *Justification: The current wording of this provision makes unclear its character. The proposed amendment removes that ambiguity, by specifying the mandatory character of either procedure with explicit references of the relevant ITU-R Recommendations.*
S56.2	§ 2 The procedures specified in Recommendation ITU-R M.492-6 should be employed except in cases of distress, urgency, or safety, in which case alternate or non-standard procedures may be used.	NOC

6 Provisions of category E (see paragraph 1 above)

S1.156	*power:* Whenever the power of a radio transmitter, etc. is referred to it shall be expressed in one of the following forms, according to the class of *emission*, using the arbitrary symbols indicated: – *peak envelope power* (*P*X or *p*X); – *mean power* (*P*Y or *p*Y); – *carrier power* (*P*Z or *p*Z). For different *classes of emission*, the relationships between *peak envelope power*, *mean power* and *carrier power*, under the conditions of normal operation and of no modulation, are contained in ITU-R Recommendations which may be used as a guide. For use in formulae, the symbol *p* denotes power expressed in watts and the symbol *P* denotes power expressed in decibels relative to a reference level.	NOC

S3.4	To the maximum extent possible, equipment to be used in a station should apply signal processing methods which enable the most efficient use of the frequency spectrum in accordance with the relevant ITU-R Recommendations. These methods include, *inter alia*, certain bandwidth expansion techniques, and in particular, in amplitude-modulation systems, the use of the single-sideband technique.	NOC
S3.7	Transmitting stations shall conform to the maximum permitted power levels for out-of-band emissions specified for certain services and classes of emission in the present Regulations. In the absence of such specified maximum permitted power levels transmitting stations should, to the maximum extent possible, satisfy the requirements relating to the limitation of the out-of-band emissions specified in the most recent ITU-R Recommendations (see Resolution 27 **(Rev.WRC-97)**).	NOC
S3.14	To ensure compliance with these Regulations, administrations shall arrange for frequent checks to be made of the emissions of stations under their jurisdiction. For this purpose, they shall use the means indicated in Article **S16**, if required. The technique of measurements and the intervals of measurements to be employed shall be, as far as is practicable, in accordance with the most recent ITU-R Recommendations.	To ensure compliance with these Regulations, administrations shall arrange for frequent checks to be made of the emissions of stations under their jurisdiction. For this purpose, they shall use the means indicated in Article **S16**, if required. The technique of measurements and the intervals of measurements to be employed should~~shall~~ be, as far as is practicable, in accordance with the most recent ITU-R Recommendations. *Justification: The combination "as far as..." and "shall" is inherently inconsistent.*
S5.474	In the band 9 200-9 500 MHz, search and rescue transponders (SART) may be used, having due regard to the appropriate ITU-R Recommendation (see also Article **S31**).	NOC

S9.50.1	In the absence of specific provisions in these Regulations relating to the evaluation of interference, the calculation methods and the criteria should be based on relevant ITU-R Recommendations agreed by the administrations concerned. In the event of disagreement on a Recommendation or in the absence of such a Recommendation, the methods and criteria shall be agreed between the administrations concerned. Such agreements shall be concluded without prejudice to other administrations.	NOC
S15.10	§ 6 The out-of-band emissions of transmitting stations should not cause harmful interference to services which operate in adjacent bands in accordance with these Regulations and which use receivers in conformity with Nos. **S3.3**, **S3.11**, **S3.12**, **S3.13** and relevant ITU-R Recommendations.	§ 6 The out-of-band emissions of transmitting stations should not cause harmful interference to services which operate in adjacent bands in accordance with these Regulations and which use receivers in conformity with Nos. **S3.3**, **S3.11**, **S3.12**~~,~~ and **S3.13**.~~and relevant ITU-R Recommendations.~~ *Justification: The broad reference to "relevant ITU-R Recommendations", with no explicit specification of the relevant references, does not serve any useful purpose.*
S15.12.1 **S15.13.1**	In this matter, administrations should be guided by the latest relevant ITU-R Recommendation.	NOC
S16.1	To assist to the extent practicable in the implementation of these Regulations, in particular to help ensure efficient and economical use of the radio-frequency spectrum and to help in the prompt elimination of harmful interference, administrations agree to continue the development of monitoring facilities and, to the extent practicable, to cooperate in the continued development of the international monitoring system, taking into account the relevant ITU-R Recommendations.[1]	NOC
S19.3	2) Where practicable and in appropriate services, identification signals should be automatically transmitted in accordance with relevant ITU-R Recommendations.	NOC

S19.23	§ 6 To the extent possible the identification signal should be transmitted in accordance with relevant ITU-R Recommendations.	NOC
S19.24	§ 7 Administrations should ensure that wherever practicable superimposed identification methods be employed in accordance with ITU-R Recommendations.	NOC
S19.35	§ 16 The Secretary-General shall be responsible for allocating additional maritime identification digits (MIDs) to administrations within the limits specified[2], provided that he is satisfied that the possibilities offered by the MIDs allocated to an administration will soon be exhausted despite judicious ship station identity assignment as outlined in Section VI, which should be in conformity with the relevant ITU-R and ITU-T Recommendations.	NOC
S19.99	§ 39 When a station[5] in the maritime mobile service or the maritime mobile-satellite service is required to use maritime mobile service identities, the responsible administration shall assign the identity to the station in accordance with the provisions described in Nos. **S19.100** to **S19.126**; in so doing, it should take into account the relevant ITU-R and ITU-T Recommendations. In accordance with No. **S20.16**, administrations shall notify the Bureau immediately when assigning maritime mobile service identities.	NOC
S19.112	*a)* [Administrations should] follow the guidelines contained in the relevant ITU-R and ITU-T Recommendations for the assignment of ship station identities;	NOC

[2] **S19.35.1** (Not reproduced).

[5] **S19.99.1** (Not reproduced).

S19.115	*d)* [Administrations should] assign one-trailing-zero or two-trailing-zero identities to vessels when they require automatic access only on a national or regional level, as defined in the relevant ITU-T Recommendations;	NOC
S19.126	2) The MID represents only the territory or geographical area of the administration assigning the group coast station call identity. The identity may be assigned to stations of one administration which are located in only one geographical region as indicated in the relevant ITU-T Recommendations.	NOC
S21.6.1 **S21.12.1** **S21.16.1**	The equality of right to operate when a band of frequencies is allocated in different Regions to different services of the same category is established in No. **S4.8**. Therefore any limits concerning inter-Regional interference which may appear in ITU-R Recommendations should, as far as practicable, be observed by administrations.	NOC
A.S22.1	In applying the provisions of this Article, the level of accepted interference (see No. **S1.168**) shall be fixed by agreement between the administrations concerned, using the relevant ITU-R Recommendations as a guide.	NOC
S22.22.2	The level of harmful interference is determined by agreement between the administrations concerned, with the guidance of the relevant ITU-R Recommendations.	NOC
S30.1	§ 1 This Chapter contains the provisions for the operational use of the global maritime distress and safety system (GMDSS), which is fully defined in the International Convention for the Safety of Life at Sea (SOLAS), 1974, as amended. Distress, urgency and safety transmissions may also be made, using Morse telegraphy or radiotelephony techniques, in accordance with the provisions of Appendix **S13** and relevant ITU-R Recommendations. Stations of the maritime mobile service, when using frequencies and techniques in conformity with Appendix **S13**, shall comply with the appropriate provisions of that Appendix.	NOC

S56.7	§ 6 Where transmission over the telecommunication channels open to public correspondence (excluding the telecommunication channels of the mobile service and of the mobile-satellite service and its feeder links) is involved, the provisions of the International Telecommunication Regulations and the relevant ITU-T Recommendations should be taken into account.	NOC

7 Provisions of category F (see paragraph 1 above)

S16.2	The international monitoring system comprises only those monitoring stations which have been so nominated by administrations in the information sent to the Secretary-General in accordance with Recommendation ITU-R SM.1139. These stations may be operated by an administration or, in accordance with an authorization granted by the appropriate administration, by a public or private enterprise, by a common monitoring service established by two or more countries, or by an international organization.	The international monitoring system comprises only those monitoring stations which have been so nominated by administrations in the information sent to the Secretary-General, following the guidelines indicated in ~~accordance with~~ Recommendation ITU-R SM.1139. These stations may be operated by an administration or, in accordance with an authorization granted by the appropriate administration, by a public or private enterprise, by a common monitoring service established by two or more countries, or by an international organization. *Justification: As the original linkage language is unclear, the proposed modification is intended to indicate the non-mandatory character of the referenced text.*

S19.83	§ 36 When stations of the maritime mobile service use selective calling devices in accordance with Recommendations ITU-R M.257-3, ITU-R M.476-5, ITU-R M.625-3 and ITU-R M.627-1, their call numbers shall be assigned by the responsible administrations in accordance with the provisions below.	§ 36 When <u>a</u> station~~s~~ of the maritime mobile service <u>is required to</u> use selective calling devices<u>, either for sequential single frequency calling equipment or for narrow-band direct printing equipment,</u>~~in accordance with Recommendations ITU-R M.257-3, ITU-R M.476-5, ITU-R M.625-3 and ITU-R M.627-1, their call numbers shall be assigned by~~ the responsible administration~~s~~ <u>shall assign call numbers to the stations</u> in accordance with the provisions below. *Justification: As the original linkage language is unclear, the proposed modification is intended to clarify the provision, without making references to the ITU-R Recommendations. The mandatory character of these Recommendations is indicated in Nos.* ***S54.2*** *(for SSFC) and in* ***S51.41*** *(for NBDP).*
S19.96A	3) Five-digit ship station selective call numbers are assigned to sequential single frequency selective calling (SSFC) equipment (as described in Recommendation ITU-R M.257-3) for calling in radiotelephony and for the phasing in of narrow-band direct printing (NBDP) equipment (as described in Recommendation ITU-R M.476-5). Within one administration the same five-digit number may be used: – for identification of ship stations fitted with both SSFC and NBDP equipment; – for identification of ship stations of two different ships fitted with either SSFC or NBDP equipment only.	3) Five-digit ship station selective call numbers are assigned to sequential single frequency selective calling (SSFC) equipment ~~(as described in Recommendation ITU-R M.257-3)~~ for calling in radiotelephony and for the phasing in of narrow-band direct printing (NBDP) equipment ~~(as described in Recommendation ITU-R M.476-5)~~. Within one administration the same five-digit number may be used: – for identification of ship stations fitted with both SSFC and NBDP equipment; – for identification of ship stations of two different ships fitted with either SSFC or NBDP equipment only. *Justification: As the linkage language is not clear, the proposed modification (deletion of references to ITU-R Recommendations) eliminates any ambiguity. The emphasis in this provision is to the use of five-digit numbers. The mandatory character of the relevant ITU-R Recommendations is indicated in Nos.* ***S54.2*** *(for SSCF) and in* ***S51.41*** *(for NBDP).*

S52.149	2) The international digital selective-calling frequencies indicated in Recommendation ITU-R M.541-8 may be used by any ship station. In order to reduce interference on these frequencies, they shall only be used when calling cannot be made on nationally assigned frequencies.	2) The international digital selective-calling frequencies indicated in Appendix **S17** (Part A, Note 1)~~Recommendation ITU-R M.541-8~~ may be used by any ship station. In order to reduce interference on these frequencies, they shall only be used when calling cannot be made on nationally assigned frequencies.
S52.188	4) Transmissions in the bands 2 170-2 173.5 kHz and 2 190.5-2 194 kHz with the carrier frequency 2 170.5 kHz and the carrier frequency 2 191 kHz, respectively, are limited to class J3E emissions and are limited to a peak envelope power of 400 W. However, on the frequency 2 170.5 kHz and with the same power limit, coast stations may also use class H2B emissions when using the selective calling system defined in Recommendation ITU-R M.257-3 and exceptionally, in Regions 1 and 3 and in Greenland, may also use class H3E for safety messages.	4) Transmissions in the bands 2 170-2 173.5 kHz and 2 190.5-2 194 kHz with the carrier frequency 2 170.5 kHz and the carrier frequency 2 191 kHz, respectively, are limited to class J3E emissions and are limited to a peak envelope power of 400 W. However, on the frequency 2 170.5 kHz and with the same power limit, coast stations may also use class H2B emissions when using the sequential single frequency selective calling system~~ defined in Recommendation ITU-R M.257-3~~ and exceptionally, in Regions 1 and 3 and in Greenland, may also use class H3E for safety messages.
S52.192	*b)* by coast stations to announce the transmission, on another frequency, of traffic lists (see Recommendation ITU-R M.1171).	*b)* by coast stations to announce the transmission, on another frequency, of traffic lists to all stations, in accordance with~~(see~~ Recommendation ITU-R M.1171~~)~~. *Justification: The broad reference to Recommendation ITU-R M.1171 is not sufficient.*
S52.213	2) In exceptional circumstances, if frequency usage according to Nos. **S52.203** to **S52.208** or No. **S52.210** is not possible, a ship station may use one of its own assigned national ship-to-shore frequencies for communication with a coast station of another nationality, under the express condition that the coast station as well as the ship station take precautions (see Recommendation ITU-R M.1171) to ensure that the use of such a frequency will not cause harmful interference to the service for which the frequency in question is authorized.	2) In exceptional circumstances, if frequency usage according to Nos. **S52.203** to **S52.208** or No. **S52.210** is not possible, a ship station may use one of its own assigned national ship-to-shore frequencies for communication with a coast station of another nationality, under the express condition that the coast station as well as the ship station take precautions~~ (see Recommendation ITU-R M.1171)~~ to ensure that the use of such a frequency will not cause harmful interference to the service for which the frequency in question is authorized. *Justification: The reference to Recommendation ITU-R M.1171 is redundant as it specifies the same condition in a slightly different language.*

8 Provisions of category G (see paragraph 1 above)

S1.153	*occupied bandwidth:* The width of a frequency band such that, below the lower and above the upper frequency limits, the *mean powers* emitted are each equal to a specified percentage ß/2 of the total *mean power* of a given *emission.* Unless otherwise specified in an ITU-R Recommendation for the appropriate *class of emission*, the value of ß/2 should be taken as 0.5%.	NOC
S1.167	*permissible interference*[3]*:* Observed or predicted *interference* which complies with quantitative *interference* and sharing criteria contained in these Regulations or in ITU-R Recommendations or in special agreements as provided for in these Regulations.	NOC
S26.6	§ 4 In selecting the technical characteristics of standard frequency and time signal transmissions, administrations shall be guided by the relevant ITU-R Recommendations.	§ 4 ~~In selecting the t~~Technical characteristics of standard frequency and time signal transmissions should be selected having due regard to ~~, administrations shall be guided by~~ the relevant ITU-R Recommendations. *Justification: As the original linkage language is unclear, the proposed modification is intended to indicate the non-mandatory character of the referenced text.*

ANNEX 6 TO CHAPTER 7

Example of hard pfd limits (Approach 1)

Under this approach, in order to protect the terrestrial services, the following pfd levels would be established. With respect to the examination of the FSS assignments under **S11.31** in Region 2, the following pfd values are not to be exceeded in any 4 kHz band, on the territory of any administration having frequency assignments in a band shared with equal rights to space and terrestrial radiocommunication services:

-148	dB(W/m^2) in 4 kHz	for 0° < θ = 5°
-148 + 0.5 (θ-5)	dB(W/m^2) in 4 kHz	for 5° = θ = 25°
-138	dB(W/m^2) in 4 kHz	for 25° = θ = 90°

where θ is the angle of arrival (degrees) on the surface of the Earth.*

It is to be noted that these levels constitute the hard limits currently contained in **S21.16** for a non-geostationary satellite network in relation to the terrestrial service.

ANNEX 7 TO CHAPTER 7

Example of pfd thresholds (Approach 2)

EXAMPLE RESOLUTION XYZ (WRC-2000)

Protection of terrestrial services in all Regions from Region 2 GSO FSS networks using the frequency band 11.7-12.2 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that, in Regions 1 and 3, the band 11.7-12.2 GHz is allocated on a co-primary status to terrestrial services and to the broadcasting-satellite service;

b) that, in Region 2, the band 11.7-12.1 GHz is allocated on a co-primary status to terrestrial services (except in the countries listed in S5.486) and to the fixed-satellite service;

c) that, in Region 2, the band 12.1-12.2 GHz is allocated on a co-primary status to terrestrial services in Peru (see S5.489) and to the fixed-satellite service;

---

* These values relate to the pfd and angles of arrival which would be obtained under free-space propagation conditions.

d) that the protection of the broadcasting-satellite service in Regions 1 and 3 from the fixed-satellite service in Region 2 is assured by Article 7 and Annex 4 to Appendix S30;

e) that the protection of the fixed-satellite service in Region 2 from the fixed-satellite service in Region 2 is assured either by S9 (S9.7 or S9.12) or S22;

f) that the protection of terrestrial services in Regions 1, 2 and 3 from non-geostationary satellite systems in the fixed-satellite service in Region 2 is assured by S21;

g) that there is a need to protect terrestrial services in Regions 1, 2 and 3 from geostationary-satellite networks in the fixed-satellite service in Region 2,

recognizing

a) that ITU-R has developed Recommendation ITU-R SF.674-1, dealing with sharing between the fixed-satellite service in Region 2 and the fixed service in the band 11.7-12.2 GHz in Region 2;

b) that the power flux-density limits contained in Article S21 (Table S21-4) and applicable to the fixed-satellite service in the band 10.7-11.7 GHz afford an adequate protection to terrestrial services;

c) that the limits referred in *recognizing b)* are 2 dB less stringent than the coordination thresholds contained in Recommendation ITU-R SF.674-1,

resolves

that coordination is requested for Region 2 geostationary FSS networks operating in the 11.7-12.2 GHz band, with any administration of Regions 1, 2 and 3 having a primary allocation to terrestrial services in the same frequency band if the power flux-density produced on its territory by a geostationary fixed-satellite space station exceeds the following thresholds:

-150	$dB(W/m^2)$ in 4 kHz	for $0° \leq \Theta \leq 5°$
$-150 + 0.5 (\Theta-5)$	$dB(W/m^2)$ in 4 kHz	for $5° < \Theta \leq 25°$
-140	$dB(W/m^2)$ in 4 kHz	for $\Theta \geq 25°$

where Θ is the angle of arrival of the incident wave above the horizontal plane, in degrees.*

MOD **S5.488** The use of the bands 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 and 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 is subject to ~~previous agreement between administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9** and **S11**)~~the provisions of Resolution **XYZ (WRC-2000)**. For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

* These values relate to the pfd and angles of arrival which would be obtained under free-space propagation conditions.

ANNEX 8 TO CHAPTER 7

Example of pfd thresholds (Approach 2)

EXTRACT OF RECOMMENDATION ITU-R SF.674-1

POWER FLUX-DENSITY VALUES TO FACILITATE THE APPLICATION OF ARTICLE 14 OF THE RADIO REGULATIONS FOR FSS IN RELATION TO THE FIXED-SATELLITE SERVICE IN THE 11.7-12.2 GHz BAND IN REGION 2

(Question ITU-R 62/4)

(1990-1997)

The ITU Radiocommunication Assembly,

considering

...

recommends

1 that in the frequency band 11.7-12.2 GHz shared between systems in the FSS in Region 2 and line-of-sight radio-relay systems, the values of pfd on the territory of the affected administrations using the FS which would be used to identify these administrations to facilitate the application of Article 14 of the RR (S9.21, RR revised by the World Radiocommunication Conference (Geneva, 1995) (WRC-95)), should be, in any 4 kHz band:

-150	$dB(W/m^2)$ in 4 kHz	for $0° \leq \theta \leq 5°$
$-150 + 0.5\ (\theta - 5)$	$dB(W/m^2)$ in 4 kHz	for $5° < \theta < 25°$
-140	$dB(W/m^2)$ in 4 kHz	for $25° \leq \theta \leq 90°$

where θ is the angle of arrival (degrees) on the surface of the Earth of the radio-frequency wave;

2 that the above values relate to the pfd and angles of arrival which would be obtained under free-space propagation conditions;

3 that the following Note should be regarded as part of this Recommendation:

NOTE 1 - Pfd limits where appropriate are contained in the RR. The values in § 1 are intended to facilitate the application of Article 14 (S9.21, RR revised by WRC-95) and are not intended as pfd limits.

ANNEX 9 TO CHAPTER 7

Example of regulatory Approach 3

MOD S5.488 The use of the bands 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 and 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7-12.2 GHz by geostationary-satellite networks in the fixed-satellite service in Region 2 is subject to previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9**, including No. **S9.21**, and **S11**). For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

CHAPTER 8

Progress of studies for future conferences

CONTENTS

8.1 Agenda item 7.2

"to recommend to the Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent Conference and on possible agenda items for future conferences"

8.1.1 Preliminary agenda for WRC-02/03

The ITU-R has commenced studies on the items identified in Resolution **722 (WRC-97)** for inclusion in the agenda for WRC-02/03 that will require preparatory work by the ITU-R. Resolution **722 (WRC-97)** includes the following items:

"1 to take appropriate action in respect of those urgent issues that were specifically requested by WRC-99;

2 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, and taking account of the results of WRC-99, to consider and take appropriate action in respect of the following topics:

2.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, taking into account Resolution **26 (Rev.WRC-97)**;

2.2 consideration of Article **S25** concerning the amateur and amateur-satellite services;

2.3 issues related to Appendix **S3**:

2.3.1 to consider the results of studies regarding the boundary between spurious and out-of-band emissions;

2.3.2 to consider the inclusion of general limits for out-of-band emissions in the Radio Regulations, in particular with regard to whether it is appropriate to do so, taking into account the results of ITU-R studies;

2.4 review of the frequency and channel arrangements in the MF and HF bands allocated on a primary basis to the maritime mobile service, taking into account the use of new digital technology, in accordance with Resolution **347 (WRC-97)**;

2.5 to review in Appendix **S2** the Table of transmitter frequency tolerances, taking into account the frequency tolerance limits specified in Recommendation ITU-R SM.1045;

2.6 to consider the status of allocations to the radiolocation service in the bands around 3 GHz and around 5.5 GHz, the date of a conference is under discussion;

2.7 sharing between the fixed-satellite service (FSS) and fixed service in the 19 GHz band, when used bidirectionally by the FSS to provide feeder links for non-geostationary-satellite orbit (non-GSO) mobile-satellite service (MSS) systems;

2.8 to consider spectrum requirements for wideband aeronautical telemetry in the band between 3 GHz and 30 GHz;

2.9 review of allocations to the space-research service (deep space) (space-to-Earth) and the inter-satellite service in the frequency range 32-32.3 GHz with a view to improving the sharing conditions between these services;

2.10 to consider Appendix **S13** and Resolution **331 (Rev.WRC-97)** with a view to their deletion and, if appropriate, consider related changes to Chapter **SVII** and other provisions of the Radio

Regulations as necessary, taking into account the continued transition to the Global Maritime Distress and Safety System (GMDSS);

2.11 to consider the results of studies, and take necessary actions relating to:

2.11.1 the exhaustion of the maritime mobile service identity numbering resource (Resolution **344 (WRC-97)**);

2.11.2 shore-to-ship distress communication priorities (Resolution **348 (WRC-97)**);

2.12 consideration of the need to realign the allocations to the amateur, amateur-satellite and broadcasting services around 7 MHz on a worldwide basis, taking into account Recommendation **718 (WARC-92)**;

2.13 examination of the adequacy of the frequency allocations for HF broadcasting from about 4 MHz to 10 MHz, taking into account the seasonal planning procedures adopted by WRC-97, and to consider bringing forward the date of availability of the HF bands allocated by WARC-92 to the broadcasting service in response to Resolution **29 (WRC-97)** and Resolution **537 (WRC-97)**;

3 to consider the results of the studies related to the following with a view to considering them for inclusion in the agendas of future conferences:

3.1 Resolution **528 (WARC-92)**;

3.2 possible allocations in the frequency bands above 275 GHz;

3.3 potential for sharing around 4 300 MHz between radio altimeters and space-based passive earth sensors;

3.4 additional allocations on a worldwide basis for the non-GSO MSS with service links operating below 1 GHz in accordance with Resolution **728 (WRC-97)**;

3.5 allocations on a worldwide basis for feeder links in bands around 1.4 GHz to the non-GSO MSS with service links operating below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolution **127 (WRC-97)**;

3.6 use of frequency adaptive systems in the MF/HF bands in accordance with Resolution **729 (WRC-97)**;

3.7 allocation of the frequency band 14.5-14.8 GHz to the FSS (Earth-to-space) in Region 3 (expansion of FSS to include other than feeder links of the broadcasting-satellite service);

4 to examine the revised ITU-R recommendations incorporated by reference in the Radio Regulations which have been communicated by the 2001 Radiocommunication Assembly, in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with the principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;

5 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the conference;

6 in accordance with Resolution **95 (WRC-97)**, to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

7 to review, and take appropriate action on, the Report from the Radiocommunication Assembly submitted in accordance with Nos. **135** and **136** of the Convention (Geneva, 1992);

8 to identify those items requiring urgent action by the radiocommunication study groups;"

8.1.2 Items formerly identified in Resolution 721 (WRC-97)

The ITU commenced studies of all items identified in Resolution **721 (WRC-97)** and has made progress on the matters listed for agenda item 8 that where deleted from the revised agenda given in Resolution **1130**. These items were:

"8.1 to consider the regulatory and technical provisions for the quasi-geostationary satellite networks;

8.2 to examine the spectrum requirements for telemetry, tracking, and telecommand of FSS networks operating with service links in the frequency bands above 17 GHz;

8.3 to review the use of the frequency band 415-526.5 kHz by the aeronautical radionavigation and maritime mobile services;

8.4 to review the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to meeting the changing needs of these services;

8.5 to consider possible extension of the allocation to the MSS (Earth-to-space) on a secondary basis in the band 14-14.5 GHz to cover aeronautical applications as stipulated in Resolution **216 (WRC-97)**;

8.6 to consider the provision of up to 3 MHz of frequency spectrum for the implementation of telecommand links in the space research and space operation services in the frequency range between 100 MHz and 1 GHz, taking into account Resolution **723 (WRC-97)**;

8.7 to consider provision of up to 6 MHz of frequency spectrum to the Earth exploration-satellite service (active) in the frequency band 420-470 MHz, in accordance with Resolution **727 (WRC-97)**;

8.8 consideration of changes to the allocations in Region 3 for the band 1 350-1 400 MHz to permit co-primary use by the fixed service."

8.1.3 Studies by the ITU-R for future conferences

The studies of the ITU-R on the items above are expected to be completed in time for the next conference after WRC-2000.

CPM-99 took note of the interim report of the Director of the Radiocommunication Bureau on the issues referred to in Resolution **29 (WRC-97)** notably:

a) information on the occupancy by the fixed and mobile services in some HF bands which were allocated by WARC-92 to the broadcasting service; and

b) status report with regard to studies on possible sharing between broadcasting and other services in the HF bands.

CPM-99 commended the Director, BR for the interim report and noted that a further report will be submitted to WRC-2000.

Progress on the following studies have been reported to the CPM.

8.1.3.1 Earth exploration-satellite service (active) in the frequency band 420-470 MHz, in accordance with Resolution 727 (WRC-97)

Preliminary ITU-R studies have presented a sharing analysis between possible EESS (active) and the amateur-satellite services in the band 430-440 MHz. This study falls within former WRC-2000 agenda item 8.7.

The discussions have shown the need for further study on this issue and clearly indicate the interest of the scientific community on one hand and the need to protect the existing services on the other.

8.1.3.2 Earth exploration-satellite service (active) in the band 5 460-5 570 MHz

Studies within ITU-R have considered the feasibility of sharing between EESS (active) and other services above the band 5 250-5 460 MHz currently allocated to EESS (active). This has drawn to the drafting of a new Recommendation on sharing in the band 5 250-5 570 MHz between the Earth exploration-satellite (active) and space research (active) services and other services allocated in this band.

The sharing studies have shown the potential for sharing between spaceborne altimeters and proposed Hiperlan systems above 5 460 MHz.

8.1.3.3 Implementation of telecommand links in the space research and space operation services in the frequency range between 100 MHz and 1 GHz, taking into account Resolution 723 (WRC-97)

This item is being currently considered by the ITU-R. As former agenda 8.6 of Resolution **721 (WRC-97)** and considering the interest on this issue, it is felt that this item could be considered in the agenda of the conference following WRC-2000.

8.1.3.4 Possible allocations in the frequency bands above 275 GHz and potential for sharing around 4 300 MHz between radio altimeters and space-based passive earth sensors

These two items have already been considered by the ITU-R and studies will be completed by the year 2002. These are included in Resolution **722 (WRC-97)** to be considered in the agendas of future conferences (items 3.2 and 3.3). It is there felt that this could be included earlier in the agenda of the conference following WRC-2000.

8.1.3.5 Sharing between high-altitude non-GSO (quasi-GSO) and non-GSO systems

ITU-R studies regarding sharing between high-altitude non-GSOs (i.e. quasi-GSOs) and lower-altitude non-GSOs, such as LEOs and MEOs are continuing. It has been noted that the large difference in orbital characteristics may impose constraints, which need to be assessed through future study by the ITU-R. This matter was included in the former agenda 8.1 of Resolution **721 (WRC-97)**.

ANNEX TO THE CPM REPORT

List of the ITU-R Recommendations related to the CPM Report to WRC-2000

Chapter 1 - IMT-2000, maritime and aeronautical issues		
ITU-R M.816-1	Framework for services supported on International Mobile Telecommunications-2000 (IMT-2000)	1997 M-series, Part 2
Recommendation ITU-R M.687-2	International Mobile Telecommunications-2000 (IMT-2000)	1997 M-series, Part 2
ITU-R M.1390	Methodology for the calculation of IMT-2000 terrestrial spectrum requirements	1997 M-series, Part 2, Sup. 1
ITU-R M.1391	Methodology for the calculation of IMT-2000 satellite spectrum requirements	1997 M-series, Part 2, Sup. 1
Recommendation ITU-R SA.1154	Provisions to protect the space research (SR), space operations (SO) and Earth-exploration satellite services (EEES) and to facilitate sharing with the mobile service in the 2 025-2 110 and 2 200-2 290 MHz bands	1997 SA-series
Recommendation ITU-R M.1036-1	Spectrum considerations for implementation of International Mobile Telecommunications-2000 (IMT-2000) in the bands 1 885-2 025 MHz and 2 110-2 200 MHz	1997 M-series, Part 2
DNR ITU-R M.[IMT-HAPS]	Minimum performance characteristics and operational conditions for HAPS operating within the IMT-2000 system in the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz	Doc. 8/115
Recommendation ITU-R RA.1031-1	Protection of the radio astronomy service in frequency bands shared with other services	1997 RA-series
Recommendation ITU-R RA.769-1	Protection criteria used for radio astronomical measurements	1997 RA-series
Recommendation ITU-R F.1242	Radio-frequency channel arrangements for digital radio systems operating in the range 1 350 MHz to 1 530 MHz	1997 F-series, Part 1
Recommendation ITU-R F.1098-1	Radio-frequency channel arrangements for radio-relay systems in the 1 900-2 300 MHz band	1997 F-series, Part 1
Recommendation ITU-R F.1243	Radio-frequency channel arrangements for digital radio systems operating in the range 2 290-2 670 MHz	1997 F-series, Part 1
Recommendation ITU-R F.283-5	Radio-frequency channel arrangements for low and medium capacity analogue or digital radio-relay systems operating in the 2 GHz band	1997 F-series, Part 1
Recommendation ITU-R F.382-7	Radio-frequency channel arrangements for radio-relay systems operating in the 2 and 4 GHz bands	1997 F-series, Part 1
Recommendation ITU-R F.701-2	Radio-frequency channel arrangements for analogue and digital point-to-multipoint radio systems operating in the frequency bands in the range 1 350 to 2 690 GHz (1.5, 1.8, 2.0, 2.2, 2.4 and 2.6 GHz)	1997 F-series, Part 1
Recommendation ITU-R F.759	Use of frequencies in the bands 500 to 3 000 MHz for radio-relay systems	1997 F-series, Part 2
Recommendation ITU-R F.389-2	Preferred characteristics of auxiliary radio-relay systems operating in the 2, 4, 6 or 11 GHz bands	1990 CCIR Volume IX, Part 1
Recommendation ITU-R F.755-1	Point-to-multipoint systems used in the fixed service	1997 F-series, Part 1
Recommendation ITU-R F.758-1	Considerations in the development of criteria for sharing between the terrestrial fixed service and other services	1997 F-series, Part 2

Recommendation ITU-R F.1334	Protection criteria for systems in the fixed service sharing the same frequency band in the 1 to 3 GHz range with the land mobile service	1997 F-series, Part 2
Recommendation ITU-R F.1094-1	Maximum allowable error performance and availability degradations to digital radio-relay systems arising from interference from emissions and radiations from other sources	1997 F-series, Part 1
Recommendation ITU-R F.1241	Performance degradation due to interference from other services sharing the same frequency bands on a primary basis with digital radio-relay systems operating at or above the primary rate and which may form part of the international portion of a 27 500 km hypothetical reference path	1997 F-series, Part 1
Recommendation ITU-R F.1331	Performance degradation due to interference from other services sharing the same frequency bands on a primary basis with analogue radio-relay systems for television	1997 F-series, Part 1
Recommendation ITU-R F.1245	Mathematical model of average radiation patterns for line-of-sight point-to-point radio-relay system antennas for use in certain coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 F-series, Part 2
Recommendation ITU-R F.1336	Reference radiation patterns of omnidirectional and other antennas in point-to-multipoint systems for use in sharing studies	1997 F-series, Part 2
Recommendation ITU-R F.699-4	Reference radiation patterns for line-of-sight radio-relay system antennas for use in coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 F-series, Part 2
Recommendation ITU-R BT.1368-1	Planning criteria for digital terrestrial television services in the VHF/UHF television bands	1997 BT-series, Supplement 2
Recommendation ITU-R BT.417-4	Minimum field strengths for which protection may be sought in planning a television service	1997 BT-series
Recommendation ITU-R BT.798-1	Digital television terrestrial broadcasting in the VHF/UHF bands	1997 BT-series
Recommendation ITU-R IS.851-1	Sharing between the broadcasting service and the fixed and/or mobile services in the VHF and UHF bands	1997 IS-series
Recommendation ITU-R BO.1130-1	Systems for digital sound broadcasting to vehicular, portable and fixed receivers for broadcasting-satellite service (sound) bands in the frequency range 1 400-2 700 MHz	1997 BO-series
Recommendation ITU-R M.1040	Public mobile telecommunication service with aircraft using the bands 1 670-1 675 MHz and 1 800-1 805 MHz	1997 M-series, Part 3
DNR ITU-R M.[8B/XA]	Protection criteria for telemetry systems in the aeronautical mobile service and mitigation techniques to facilitate sharing with geostationary broadcasting-satellite and mobile-satellite services in the bands 1 452-1 525 MHz and 2 310-2 360 MHz	Doc. 8/73
Recommendation ITU-R M.1044-1	Frequency sharing criteria in the amateur and amateur-satellite services	1997 M-series, Part 6
Recommendation ITU-R SA.1016	Sharing considerations relating to deep-space research	1997 SA-series
Recommendation ITU-R SA.1027-3	Sharing and coordination criteria for space-to-earth data transmission systems in the earth exploration-satellite and meteorological-satellite services using satellites in low-Earth orbit	Doc. 7/BL/6
Recommendation ITU-R SA.1157	Protection criteria for deep-space research	1997 SA-series
Recommendation ITU-R M.1313	Technical characteristics of maritime radionavigation radars	1997 M-series, Part 4

Recommendation ITU-R M.629	Use for the radionavigation service of the frequency bands 2 900-3 100 MHz, 5 470-5 650 MHz, 9 200-9 300 MHz, 9 300-9 500 MHz and 9 500-9 800 MHz	1997 M-series, Part 4
DNR ITU-R M.[RAD.CHAR2]	Characteristics of radionavigation and meteorological radars and protection criteria in the frequency band 2 700-2 900 MHz	Doc. 8/68
DNR ITU-R M.[RAD.CHAR3]	Technical and operational characteristics and protection criteria of radiodetermination and meteorological radars in the 2 900-3 100 MHz band	Doc. 8/56
DNR ITU-R M.[RAD.CHAR4]	Characteristics of and protection criteria for radars operating in the radiodetermination service in the frequency band 3 100-3 700 MHz	Doc. 8/69
DNR ITU-R M.[RAD.PROC]	Procedures for determining the potential for interference between radars operating in the radiodetermination service and systems in other services	Doc. 8/67
Recommendation ITU-R M.1141-1	Sharing in the 1-3 GHz frequency range between non-geostationary space stations operating in the mobile-satellite service and stations in the fixed service	1997 M-series, Part 5
Recommendation ITU-R M.1142-1	Sharing in the 1-3 GHz frequency range between geostationary space stations operating in the mobile-satellite service and stations in the fixed service	1997 M-series, Part 5
Recommendation ITU-R M.1084-3	Interim solutions for improved efficiency in the use of the band 156-174 MHz by stations in the maritime mobile service	1997 M-series, Part 3, Sup.1
Recommendation ITU-R M.1308	Evolution of land mobile systems towards IMT-2000	1997 M-series, Part 2
Recommendation ITU-R M.1312	A long-term solution for improved efficiency in the use of the band 156-174 MHz by stations in the maritime mobile service	1997 M-series, Part 3
Chapter 2 - Mobile-satellite and radionavigation-satellite services		
Recommendation ITU-R M.1089	Technical considerations for the coordination of mobile-satellite systems supporting the aeronautical mobile-satellite (R) service (AMS(R)S)	1997 M-series, Part 5
Recommendation ITU-R M.1180	Availability of communication circuits in the aeronautical mobile-satellite (R) services (AMS(R)S)	1997 M-series, Part 5
Recommendation ITU-R M.1229	Performance objectives for the digital aeronautical mobile-satellite service (AMSS) channels operating in the bands 1 525 to 1 559 MHz and 1 626.5 to 1 660.5 MHz not forming part of the ISDN	1997 M-series, Part 5
Recommendation ITU-R M.1233	Technical considerations for sharing satellite network resources between the mobile-satellite service (MSS) (other than the aeronautical mobile-satellite (R) service (AMS(R)S)) and AMS(R)S	1997 M-series, Part 5
Recommendation ITU-R M.1234	Permissible level of interference in a digital channel of a geostationary satellite network in the aeronautical mobile-satellite (R) service (AMS(R)S) in the bands 1 545 to 1 555 MHz and 1 646.5 to 1 656.5 MHz and its associated feeder links caused by other networks of this service and the fixed-satellite service	1997 M-series, Part 5
Recommendation ITU-R M.1088	Considerations for sharing with systems of other services operating in the bands allocated to the radionavigation-satellite service	1997 M-series, Part 5
Recommendation ITU-R M.1317	Considerations for sharing between systems of other services operating in bands allocated to the radionavigation-satellite and aeronautical radionavigation services and the global navigation satellite system (GLONASS-M)	1997 M-series, Part 5
Recommendation ITU-R M.1318	Interference protection evaluation model for the radionavigation-satellite service in the 1 559-1 610 MHz band	1997 M-series, Part 5

Recommendation ITU-R F.759	Use of frequencies in the band 500 to 3 000 MHz for radio-relay systems	1997 F-series, Part 2
DNR ITU-R [RNSS.CHAR]	Technical and performance characteristics of current and planned RNSS (space-to-earth) and ARNS receivers to be considered in interference studies in the band 1 559-1 610 MHz	Doc. 8/83
DRR ITU-R M.1184	Technical characteristics of mobile satellite systems in the frequency bands below 3 GHz for use in developing criteria for sharing between the mobile-satellite service (MSS) and other services	Doc. 8/47
Recommendation ITU-R M.1343	Essential technical requirements of mobile earth stations for global non-geostationary mobile-satellite service systems in the bands 1-3 GHz	1997 M-series, Part 5
Recommendation ITU-R M.1389	Methods for achieving coordinated use of multiple non-GSO MSS systems below 1 GHz and sharing with other services in existing MSS allocations	1997 M-series, Part 5, Sup.1
DNR ITU-R M.[RNSS.ISS]	Technical characteristics and performance requirements of current and planned RNSS (space-to-space) receivers to be considered in interference studies in the bands 1 215-1 260 MHz and 1 559-1 610 MHz	Doc. 8/85
DRR ITU-R SA.1158-2	Sharing of the 1 675-1 710 MHz band between the meteorological-satellite service (space-to-Earth) and the mobile-satellite service (Earth-to-space)	Doc. 7/BL/10
Recommendation ITU-R SA.1262	Sharing and coordination criteria for meteorological aids in the 400.15-406 MHz and 1 668.4-1 700 MHz bands	1997 SA-series
DNR ITU-R M.[8D.SARP]	Protection criteria for Cospas-Sarsat search and rescue processors (SARP) in the band 406-406.1 MHz	Doc. 8/84
DNR ITU-R M. [RAD.CHAR1]	Characteristics of and protection criteria for radars operating in the radiodetermination service in the frequency band 1 215-1 400 MHz	Doc. 8/66
DRR ITU-R M.1184	Technical characteristics of mobile satellite systems in the frequency bands below 3 GHz for use in developing criteria for sharing between the mobile-satellite service (MSS) and other services	Doc. 8/47
DRR ITU-R M.1039-1	Co-frequency sharing between stations in the mobile service below 1 GHz and FDMA non-geostationary-satellite orbit (non-GSO) mobile earth stations	Doc. 8/53
DRR ITU-R SA.1258-1	Sharing of the frequency band 401-403 MHz between the meteorological-satellite service, earth exploration-satellite service and meteorological aids service	Doc. 7/BL/5
Recommendation ITU-R SA.1165-1	Technical characteristics and performance criteria for radiosonde systems in the meteorological aids service	1997 SA-series
Recommendation ITU-R RA.769-1	Protection criteria used for radioastronomical measurements	1997 RA-series
Recommendation ITU-R P.531-4	Ionospheric propagation data and prediction methods required for the design of satellite services and systems	1997 P-series, Part 2
Recommendation ITU-R S.1342	Method for determining coordination distances, in the 5 GHz band, between the international standard microwave landing system and non-geostationary mobile-satellite service stations providing feeder uplink services	1997 S-series

Chapter 3 - Non-GSO FSS issues		
DNR ITU-R S. [Doc. 4/60(Rev.1)]	Determination of the coordination area for earth stations operating with non-geostationary space stations with respect to earth stations operating in the reverse direction in frequency bands allocated bidirectionally to the fixed-satellite service	Doc. 4/BL/17
DNR ITU-R S.[Doc. 4/65]	Methods to enhance sharing between non-GSO FSS systems (except MSS feeder links) in the frequency bands between 10-30 GHz	Doc. 4/BL/20
DRR ITU-R S.1323 [4/69]	Maximum permissible levels of interference in a satellite network (GSO/FSS; non-GSO/FSS; non-GSO/MSS feeder links) in the fixed-satellite service caused by other codirectional networks below 30 GHz	Doc. 4/BL/23
Recommendation ITU-R S.1328	Satellite system characteristics to be considered in frequency sharing analyses between GSO and non-GSO satellite systems in the fixed-satellite service including feeder links for the mobile-satellite service	1997 S-series
DNR ITU-R S.[Doc. 4/57]	Reference FSS earth-station radiation patterns for use in interference assessment involving non-GSO satellites in frequency bands between 10.7 GHz and 30 GHz	Doc. 4/BL/14
Recommendation ITU-R S.672-4	Satellite antenna radiation pattern for use as a design objective in the fixed-satellite service employing geostationary satellites	1997 S-series
DRR ITU-R S.524-5 [4/66]	Maximum permissible levels of off-axis e.i.r.p. density from earth stations in GSO network operating in the fixed-satellite service transmitting in the 6, 14 and 30 GHz frequency bands	Doc. 4/66
DNR ITU-R BO.[11/138]	Protection of the broadcasting-satellite service in the 12 GHz band and associated feeder links in the 17 GHz band from interference caused by non-GSO FSS systems	Doc. 11/BL/30
DNR ITU-R BO.[11/137]	Reference BSS earth station antenna patterns for use in interference assessment involving non-geostationary satellites in frequency bands covered by Appendix **S30**	Doc. 11/BL/29
Recommendation ITU-R F.1245	Mathematical model of average radiation patterns for line-of-sight point-to-point radio-relay system antennas for use in certain coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 SF-series, Part 2
Recommendation ITU-R SF.1395	Minimum propagation attenuation due to atmospheric gases for use in frequency sharing studies between the fixed-satellite service and the fixed service	Doc. 4-9/BL/1
DNR ITU-R F.[9/1011]	Interference criteria to protect the fixed service from aggregate interference from other services sharing the 10.7-12.75 GHz band on a co-primary basis	Doc. 9/1011
Rec. ITU-R F.[9/1012]	Interference criteria to protect the fixed service from aggregate interference from other services sharing the 17.7-19.3 GHz band on a co-primary basis	Doc. 9/1012
Recommendation ITU-R F.1108-2	Determination of the criteria to protect fixed service receivers from the emissions of space stations operating in non-geostationary orbits in shared frequency bands	1997 F-series, Part 2
Rec. ITU-R SF.[4-9/1007]	Maximum allowable values of power flux-density produced at the Earth's surface by non-geostationary satellites in the fixed-satellite service operating in the 17.7-19.3 GHz band	Doc. 4-9/1007

Recommendation ITU-R SF.406-8	Maximum equivalent isotropically radiated power of radio-relay system transmitters operating in the frequency bands shared with the fixed-satellite service	1997 SF-series
Recommendation ITU-R S.1068	Fixed-satellite and radiolocation/radionavigation services sharing in the band 13.75 to 14 GHz	1997 S-series
Recommendation ITU-R SA.1155	Protection criteria related to the operation of data relay satellite systems	1997 SA-series
DNR ITU-R BO.[11/136]	Functional description to be used in developing software tools for determining conformity of non-GSO FSS networks with limits contained in Article **S22** of the Radio Regulations	Doc. 11/153
Recommendation ITU-R S.672-4	Satellite antenna radiation pattern for use as a design objective in the fixed-satellite service employing geostationary satellites	1997 S-series
DNR ITU-R SF.[Doc. 4-9S/AI]	Maximum allowable values of power flux-density produced at the Earth's surface by non-geostationary satellites in the fixed-satellite service operating in the 10.7-12.75 GHz band	Doc. 4-9/1006
	Chapter 4 - Space science services and radio astronomy	
Recommendation ITU-R RA.314-8	Preferred frequency bands for radioastronomical measurements	1997 RA-series
Recommendation ITU-R RA.769-1	Protection criteria used for radioastronomical measurements	1997 RA-series
Recommendation ITU-R RA.1031-1	Protection of the radio astronomy service in frequency bands shared with other services	1997 RA-series
Recommendation ITU-R RA.1272	Protection of radio astronomy measurements above 60 GHz from ground based interference	1997 RA-series
Recommendation ITU-R SA.515-3	Frequency bands and bandwidths used for satellite passive sensing	1997 SA-series
Recommendation ITU-R SA.1028-1	Performance criteria for satellite passive remote sensing	1997 SA-series
Recommendation ITU-R SA.1029-1	Interference criteria for satellite passive remote sensing	1997 SA-series
Recommendation ITU-R SA.1416	Sharing between spaceborne passive sensors and the inter-satellite service operating near 118 and 183 GHz	Doc. 7/BL/18
Recommendation ITU-R RA.611-2	Protection of the radio astronomy service from spurious emissions	1997 RA-series
Recommendation ITU-R F.761	Frequency sharing between the fixed service and passive sensors in the band 18.6 to 18.8 GHz	1997 F-series, Part 2
Recommendation ITU-R F.699-4	Reference radiation patterns for line-of-sight radio-relay system antennas for use in coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 F-series, Part 2
Recommendation ITU-R S.465-5	Reference earth-station radiation pattern for use in coordination and interference assessment in the frequency range from 2 to about 30 GHz	1997 S-series
Recommendation ITU-R S.580-5	Radiation diagrams for use as design objectives for antennas of earth stations operating with geostationary satellites	1997 S-series
Recommendation ITU-R S.1328	Satellite system characteristics to be considered in frequency sharing analyses between GSO and non-GSO satellite systems in the fixed-satellite service including feeder links for the mobile-satellite service	Doc. 4/BL/3 + 4/BL/15

Chapter 5 - Appendices S30 and S30A		
DRR ITU-R BO.1293	Protection masks and associated calculation methods for interference into broadcast satellite systems involving digital emissions	Doc. 11/109 (Rev.1)
DNR ITU-R BO. [Doc. 11/116]	Improved patterns for fast roll-off satellite transmit antenna of the Regions 1 and 3 BSS Plan of Appendix **S30**	Doc. 11/BL/31
DNR 11/155		Doc. 11/155

Chapter 6 - Fixed and fixed-satellite services		
Recommendation ITU-R F.697-2	Error performance and availability objectives for the local-grade portion at each end of an ISDN connection at a bit rate below the primary rate utilizing digital radio-relay systems	1997 F-series, Part 1
Recommendation ITU-R F.755-1	Point-to-multipoint systems used in the fixed service	1997 F-series, Part 1
DRR ITU-R F.758-1	Considerations in the development of criteria for sharing between the terrestrial fixed service and other services	Doc. 9/1022
Recommendation ITU-R F.1189-1	Error-performance objectives for constant bit rate digital paths at or above the primary rate carried by digital radio-relay systems which may form part or all of the national portion of a 27 500 km hypothetical reference path	1997 F-series, Part 1
Recommendation ITU-R F.1102	Characteristics of radio-relay systems operating in frequency bands above about 17 GHz	1997 F-series, Part 1
Recommendation ITU-R F.1400	Performance and availability requirements and objectives for fixed wireless access (FWA) to PSTN	Doc. 9/BL/13
Recommendation ITU-R F.699-4	Reference radiation patterns for line-of-sight radio-relay system antennas for use in coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 F-series, Part 2
Recommendation ITU-R F.1245	Mathematical model of average radiation patterns for line-of-sight point-to-point radio-relay system antennas for use in certain coordination studies and interference assessment in the frequency range from 1 to about 40 GHz	1997 F-series, Part 2
Recommendation ITU-R F.1336	Reference radiation patterns of omnidirectional and other antennas in point-to-multipoint systems for use in sharing studies	1997 F-series, Part 2
DRR ITU-R F.1097	Interference mitigation options to enhance compatibility between radar systems and digital radio-relay systems	Doc. 9/1020
Recommendation ITU-R F.1333	Estimation of the actual elevation angle from a station in the fixed service towards a space station taking into account atmospheric refraction	1997 F-series, Part 2
Recommendation ITU-R SA.1157	Protection criteria for deep-space research	1997 SA-series
Recommendation ITU-R SA.509-2	Generalized space research earth station antenna radiation pattern for use in interference calculations, including coordination procedures	1997 SA-series, Supplement 1
Recommendation ITU-R SA.609-1	Protection criteria for telecommunication links for manned and unmanned near-Earth research satellites	1997 SA-series
Recommendation ITU-R IS.847-1	Determination of the coordination area of an earth station operating with a geostationary space station and using the same frequency band as a system in a terrestrial service	1997 IS-series

Recommendation ITU-R P.452-8	Prediction procedure for the evaluation of microwave interference between stations on the surface of the Earth at frequencies above about 0.7 GHz	1997 P-series, Part 2
Recommendation ITU-R P.618-5	Propagation data and prediction methods required for the design of Earth-space telecommunication systems	1997 P-series, Part 2
DRR ITU-R P.620-3	Propagation data required for the evaluation of coordination distances in the frequency range 100 MHz to 105 MHz	Doc. 3/BL/36
Recommendation ITU-R P.676-3	Attenuation by atmospheric gases	1997 P-series, Part 1
Recommendation ITU-R RA.769-1	Protection criteria used for radioastronomical measurements	1997 RA-series
Recommendation ITU-R SA.1029-1	Interference criteria for satellite passive remote sensing	1997 SA-series
Recommendation ITU-R S.672-4	Satellite antenna radiation pattern for use as a design objective in the fixed-satellite service employing geostationary satellites	1997 S-series
DNR F.[Doc. 9/1015]	Deployment characteristics of fixed service systems in the band 37-40 GHz for use in sharing studies	Doc. 9/1015
Recommendation ITU-R SA.1344	Preferred frequency bands and bandwidths for the transmission of space VLBI data	1997 SA-series, Supplement 1
Recommendation ITU-R SA.1015	Bandwidth requirements for deep-space research	1997 SA-series
Recommendation ITU-R M.1316	Principles and a methodology for frequency sharing in the 1 610.6-1 613.8 and 1 660-1 660.5 MHz bands between the mobile-satellite service (Earth-to-space) and the radio astronomy service	1997 M-series, Part 5
DNR ITU-R SF.[Doc. 4-9/1008]	Maximum allowable values of power flux-density at the surface of the Earth produced by non-geostationary satellites in the fixed-satellite service operating in the 37.5-40.5 GHz and 40.5-42.5 GHz bands to protect the fixed service	Doc. 4-9/1008
Recommendation ITU-R SA.1259	Feasibility of sharing between spaceborne passive sensors and the fixed service from 50 to 60 GHz	1997 SA-series
Recommendation ITU-R SA.515-3	Frequency bands and bandwidths used for satellite passive sensing	1997 SA-series
DNR ITU-R F.[Doc. 9/1013]	Radio-frequency channel arrangement for radio-relay systems in the fixed service in the band 51.4-52.6 GHz	Doc. 9/1013
DNR ITU-R F.[Doc. 9/1014]	Radio-frequency channel arrangements for systems in the fixed service in the band 55.78-59 GHz	Doc. 9/1014
Recommendation ITU-R RA.517-2	Protection of the radio astronomy service from transmitters in adjacent bands	1997 RA-series
Recommendation ITU-R RA.611-2	Protection of the radio astronomy service from spurious emissions	1997 RA-series
Recommendation ITU-R RA.1237	Protection of the radio astronomy service from unwanted emissions resulting from applications of wideband digital modulation	1997 RA-series
Recommendation ITU-R RA.314-8	Preferred frequency bands for radio astronomical measurements	1997 RA-series
Recommendation ITU-R SM.329-7	Spurious emissions	Doc. 1/BL/11
Recommendation ITU-R SA.1344	Preferred frequency bands and bandwidths for the transmission of space VLBI data	1997 SA-series, Supplement 1

Recommendation ITU-R SA.1396	Protection criteria for the space research service in the 37-38 and 40-40.5 GHz bands	Doc. 7/BL/2
Recommendation ITU-R SA.1015	Bandwidth requirements for deep-space research	1997 SA-series
Recommendation ITU-R M.1316	Principles and a methodology for frequency sharing in the 1 610.6-1 613.8 and 1 660-1 660.5 MHz bands between the mobile-satellite service (Earth-to-space) and the radio astronomy service	1997 M-series, Part 5
DNR ITU-R F.[Doc. 9/1017]	Preferred characteristics of systems in the fixed service using high altitude platforms operating in the 47.2-48.2 GHz band	Doc. 9/1017
DNR ITU-R F.[Doc. 9/1018]	Coordination distance for systems in the fixed service involving high-altitude platform stations sharing the same frequency band with other systems in fixed service	Doc. 9/1018

ANNEX

Introduction of radionavigation-satellite service (RNSS) in the band 960-1 215 MHz

Agenda *resolves* 1.15.1: to consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments

1 Introduction

1.1 Proposals have been developed to introduce in the frequency range 960-1 215 MHz an allocation to the radionavigation-satellite service (RNSS) in the space-to-Earth direction. This portion of the band is used for the ICAO standardized distance measuring equipment (DME) system on a global basis. DME provides the main means for navigation of aircraft operating in the *en route* and approach phase of flight. DME/P (where the “P” stands for precise distance measurement) is used in conjunction with the microwave landing system (MLS) during the final approach and landing phase of flight.

2 Protection

2.1 Protection of DME is a necessary condition for the introduction of RNSS. An allocation to RNSS needs to satisfy the following regulatory provisions:

a) that RNSS shall not cause harmful interference to any aeronautical radionavigation service (ARNS) system operating in the band 960-1 215 MHz;

b) that RNSS shall not claim protection from any current and future ARNS system operating in the band 960-1 215 MHz; and

c) that a provisional power flux-density (pfd) limit at the Earth’s surface shall be established to secure protection of DME until the results of further studies enable a definitive figure to be agreed.

2.2 In addition, in order to minimize any adverse effect that the use of part of the band 1 151-1 215 MHz by the RNSS can have on the current operations in the ARNS, the allocation to RNSS should be made in the smallest band required, and in any case, not more than 48 MHz.

2.3 The results of a preliminary analysis by ICAO have shown that the final value for the maximum aggregate pfd level in the band allocated to RNSS should be in the order of –115 to –119 dBW/m^2/MHz. A final value can be established only after an in-depth analysis of the various sources of interference to which the DME is subject.

2.4 The pfd limits indicated in paragraph 2.3 represent the aggregate level of interference of all RNSS systems sharing the same spectrum. As an example, in the case of three satellite constellations operating in the same frequency band, the pfd per system would have to be 5 dB lower than the aggregate pfd limit referred to in Section 2.3 above.

2.5 Should more DME/P channels be required in the future, in addition to those currently assigned, additional protection margin would be required for the protection of the new channels. The receiver sensitivity threshold for DME/P is 3 dB lower than that for a DME and the receiver bandwidth is in the order of 1 to 3 MHz. This would add in total about –4.8 dB to –9.8 dB to the pfd limits referred to in Sections 2.3 and 2.4 above.

3 Conclusion

3.1 As a result of the preliminary work in ICAO to ensure protection of current operations of DME in the band 960-1 215 MHz, a provisional pfd limit for an RNSS allocation in this band should be in the range of –115 to –119 dBW/m^2/MHz for the aggregate interference from all RNSS systems operating in the same spectrum.

ANNEX

Use of the band 2 700-2 900 MHz by the aeronautical radionavigation service

Agenda item 1.6.1 - review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary

1 Introduction

1.1 This paper addresses issues concerning the introduction of a mobile service in the band 2 700-2 900 MHz. This band is allocated to the aeronautical radionavigation service on a primary basis and used for terminal approach radar (airport radar) and radars for meteorological purposes. In addition, in Canada, this band is allocated to the maritime radionavigation service for use by shore-based radar (RR S5.424 refers).

2 Current use of the band 2 700-2 900 MHz

2.1 The band 2 700-2 900 MHz is heavily used for air traffic control (surveillance) purposes by primary radar systems on a global basis. In addition, this band is used for meteorological radar, providing meteorological information for aeronautical and other services.

2.2 Most of today’s radars utilize two discrete frequencies to provide for frequency diversity in order to improve the performance of the system. Normally, radar stations are equipped with dual systems and each system is tuned to one of these frequencies. Furthermore, in order to satisfy requirements for adequate near and far detection of aircraft, many of these radar systems provide for more than one set of frequencies, thus increasing the bandwidth required for one single radar system accordingly.

2.3 Technical requirements for radar stations are normally determined on a national basis and it is difficult and speculative to agree on a model of a typical radar station which, when applied in interference assessment activities, can be used to provide for a typical sharing scenario.

2.4 The aeronautical use of the band 2 700-2 900 MHz is expected to increase significantly over the next ten years and to continue well beyond 2010. It is of paramount importance to aviation that the currently available spectrum for radar stations is maintained and that no additional restrictions be placed on future frequency assignments for radar stations. It has been considered extremely difficult, if not impossible, to relocate radar stations from the band 2 700-2 900 MHz to other frequency bands. Such relocation would also involve considerable costs for administrations providing air traffic control facilities. Typically, these radar stations are installed on busy airports, which are normally situated in areas of high population density. The operational range extends to 60-100 nautical miles.

3 Conclusions

3.1 Studies in ICAO show that sharing of aeronautical spectrum, used by radar systems, with (non-aeronautical) mobile systems is not feasible. One important reason for this position is the fact that the widespread and constantly growing use of mobile stations cannot be adequately controlled while maintaining the protection of aeronautical radar stations with the availability, reliability and continuity required for aviation.

3.2 ITU-R Study Group 8 has recently adopted Recommendation ITU-R M.[RAD.CHAR2] containing characteristics of radionavigation and meteorological radars and protection criteria in the frequency band 2 700-2 900 MHz. Also relevant to the protection of radar systems is Recommendation ITU-R M.[RAD.PROC] containing procedures for determining the potential for interference between radars operating in the radiodetermination service and systems in other services which was also adopted by Study Group 8. These Recommendations have to be used when assessing compatibility with other systems, taking into consideration adequate safety margins.

ANNEX

Aeronautical access to the satellite bands 1 545-1 555 MHz and 1 646.5-1 656.5 MHz

Agenda item 1.10 - to consider results of ITU-R studies carried out in accordance with Resolution 218 (WRC-97) and take appropriate action on this subject

1 Introduction

1.1 The ICAO position on WRC-2000 agenda *resolves* 1.10 is stated in Document WRC2000/4, paragraph 3.11.6. The purpose of this addendum is to provide additional supporting material on the issues to be discussed by the Conference.

2 Background

2.1 WRC-97 replaced the exclusive allocation to the AMS(R)S in the bands 1 545-1 555 MHz and 1 646.5-1 656.5 MHz with a “generic” allocation to the MSS and with footnote S5.357A. It was then recognized by WRC-97 (Resolution 218 refers) that the potential consequences of the new allocation needed to be assessed, and that further action would need to be taken.

2.2 The consequences have now become clear. A number of MSS systems that do not provide AMS(R)S are using spectrum in the former AMS(R)S band. It is expected that the potential growth of AMS(R)S could be compromised due to the lack of guarantees about the long-term availability of the bands. Urgent action is therefore required in order to develop a suitable regulatory framework to support further development of the service.

3 AMS(R)S spectrum requirements

3.1 Today, AMS(R)S is in operational use worldwide for such applications as automatic dependent surveillance (ADS) and controller-pilot data link communications (CPDLC), and the level of implementation is growing. This growth trend is in line with the projected spectrum requirements identified by the International Air Transport Association (IATA) and ICAO and submitted to ITU-R during the preparation to the WRC-2000. However, the full extent of the planned future expansion of AMS(R)S may be stifled due to the increasing congestion being experienced in the bands.

4 Results of the ITU studies

4.1 The ITU studies carried out in accordance with Resolution 218 have been unable to agree on a definitive approach to address the potentially serious problems ahead. They have assumed that the current approach (see section 5) may be acceptable in the short to medium time-frame. The investigation of longer term solutions has been deferred to further studies. The problem with these conclusions is twofold:

a) the current approach has a number of difficulties which will make it ineffective to deal with all but today's immediate needs; and

b) longer term solutions need to be defined now, in order for them to be implemented in time to meet the need when it arises.

5 Difficulties with the current approach

5.1 The approach currently followed to cater for AMS(R)S spectrum requirements has been termed "capacity planning". It is reported that the process consists of periodical reviews of current spectrum sharing arrangements in the band, performed by some satellite system operators, assisted by the respective administrations.

5.2 The current approach does succeed in accommodating today's relatively modest AMS(R)S spectrum requirements.

5.3 Nevertheless, difficulties with the current approach will arise as soon as spectrum congestion will increase and additional AMS(R)S spectrum will be required to accommodate the growth of the service. In such a situation, footnote S5.357A implies that current non-AMS(R)S operators may need to vacate spectrum already coordinated (and possibly in operational use) to satisfy new AMS(R)S requirements. However, no regulatory procedure or mechanism has been defined so far to provide a positive assurance that this action can be implemented as required.

5.4 The current approach also lacks transparency. The results of the periodical coordination process which takes place among a limited number of administrations and system operators are not made available to ITU and are not in the public domain. The organizations invited by Resolution 218 to participate in the related ITU-R studies on the issue (ICAO, IMO and the International Association of Lighthouse Authorities (IALA)) are not allowed to participate in the process as observers, and are not informed of the results.

5.5 It is felt that a documented record of the results of the process needs to be maintained (preferably within ITU). Access to the record should be possible for any administration or concerned international organization.

5.6 The difficulties discussed in this section severely undermine the confidence that the international civil aviation community has in the current approach, and justify the need for urgent action on the matter.

6 Comments on WRC-2000 proposals

6.1 A number of proposals have been presented to this Conference on this agenda item. None of them supports what is obviously the most effective approach to meet the requirements of the AMS(R)S (albeit not necessarily the most efficient in the short to medium term), i.e. the reinstatement of an exclusive allocation.

6.2 Within the constraints of the existing "generic" allocation, some proposals focus only on a procedural approach, whereby the coordination process is strengthened and accommodation of the needs of the AMS(R)S is attempted through periodic coordination exercises.

6.3 Other proposals focus only on technical solutions, whereby inter-system prioritization and pre-emption techniques are developed to enable dynamic spectrum reassignment among operators to cater for the needs of AMS(R)S on a real-time basis.

6.4 It is considered that each of these two approaches is incomplete if followed in isolation.

6.5 Strengthening the current coordination process to address the concerns expressed in section 5 could achieve some results in the short to medium time-frame. It is, however, unlikely that, in the longer term, the requirements of the AMS(R)S could be met with the necessary reliability and availability in the absence of technical means to ensure that a more flexible use of spectrum is implemented among the various MSS and AMS(R)S systems operating in the band.

6.6 Conversely, the study of techniques allowing dynamic spectrum reassignment among operators, in the absence of effective measures to strengthen the coordination process in the short to medium term, would be unlikely to result in the development of a timely solution. The burden of implementation of a novel and complex technical solution involving close cooperation between competing satellite network operators in such a critical domain as frequency management could only be justified in practical terms if all procedural avenues have been fully exploited.

6.7 Instead, it is considered that the two approaches are complementary and need to be pursued in parallel. Such a parallel approach has been proposed to the Conference in Document WRC2000/20 (APT common proposals for the work of the Conference), and is supported by ICAO as the one that most closely approximates the requirements of the international civil aviation community, in the absence of proposals to reinstate the exclusive allocation.

7 Conclusion

7.1 The perceived “lack of efficiency” of the pre-WRC-97 regulatory regime, has merely been replaced by the “lack of effectiveness” of the current regime, which fails to provide a stable framework for the development of the service and jeopardizes the substantial investments made by aviation to foster such development. Unless technical and regulatory measures along the lines of those proposed in Document WRC2000/20 are put in place as a matter of urgency, the growth of AMS(R)S will be stifled and the safety, regularity and efficiency of international civil aviation will be adversely affected.

Note by the Secretary-General

ICAO POSITION FOR THE CONFERENCE

I have the honour to bring to the attention of the Conference, at the request of the Secretary-General of the International Civil Aviation Organization (ICAO), Corrigendum 1 to the information paper contained in Document 4.

Yoshio UTSUMI
Secretary-General

Annex: 1

ANNEX

1 Update to the ICAO position

1.1 In the light of progress made by administrations and regional telecommunication organizations on the development of proposals for WRC-2000, ICAO has made the following updates to the ICAO position with respect to ITU WRC-2000.

Please *replace* the text in Section 3.17 of Document WRC2000/4 with the following:

"3.17 **To consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments**

3.17.1 The allocation to the radionavigation-satellite service in the band 1 559-1 610 MHz supports operations of GLONASS and GPS, presently defined elements of the ICAO GNSS. Adequate spectrum for GNSS evolution or to enhance the current use of GNSS is needed.

3.17.2 **Frequency band 960-1 215 MHz**

3.17.2.1 Adequate spectrum for the radionavigation-satellite service (RNSS) in this band should be made available with provisions which protect the current usage of this band by the aeronautical radionavigation service (ARNS), such as ACAS, DME and SSR. RNSS systems should neither cause harmful interference to the ARNS nor claim protection from the ARNS. Studies in ITU should be undertaken to assess compatibility between the ARNS and the RNSS. Any allocation to the RNSS in this band should be limited to the smallest portion necessary.

3.17.3 **Frequency band 5 000-5 150 MHz**

3.17.3.1 There are no objections to introducing an allocation to the RNSS in the band 5 000-5 030 MHz, as this band is not planned for future use by the ARNS.

3.17.3.2 As studies have shown that MLS and RNSS cannot share the same spectrum, an allocation to the RNSS in the band 5 030-5 150 MHz needs to be opposed in order to safeguard spectrum requirements for MLS which are subject to review in ITU in 2003.

3.17.4 **ICAO position**

3.17.4.1 Introduction of the RNSS in the band 960-1 215 MHz can be supported subject to the introduction of regulatory provisions in the Radio Regulations which protect the aeronautical radionavigation service. ITU studies on technical requirements to obtain compatibility are required.

3.17.4.2 Introduction of RNSS in the band 5 000-5 030 MHz is acceptable. Introduction of RNSS in the band 5 030-5 150 MHz cannot be supported."

ANNEX

ICAO POSITION FOR THE ITU WRC-2000

SUMMARY

This document reviews the agenda for the ITU WRC-2000, discusses points of aeronautical interest and provides the ICAO position for each.

CONTENTS

1. INTRODUCTION

1.1 This document addresses the ICAO position on issues of interest to international civil aviation to be decided at the ITU World Radiocommunication Conference (2000) (WRC-2000).

2. SPECTRUM REQUIREMENTS FOR INTERNATIONAL CIVIL AVIATION

2.1 The safety of air operations is vitally dependent on the availability of communications and navigation services that are reliable and free from harmful interference. Continuous contact between pilot and ground with a safety message every few minutes in high-traffic density conditions is necessary to provide an air traffic service and to avoid collision in the air. Systems for navigation must be available for all phases of flight. Satellite systems for use in aircraft are now a fully mature technology and are foreseen to provide practical and realizable benefits, which can materially contribute to operational enhancements. Future strategies, based on an increased use of space-based systems, have been agreed as international civil aviation policy through the principles established in the ICAO communications, navigation, and surveillance/air traffic management (CNS/ATM) systems. The associated high reliability and availability requirements demand special conditions to avoid harmful interference to these systems.

2.2 For the future, the radio frequency spectrum needs for civil aviation arising from the increased growth in air transport is stable, and no major adjustments in the current allocations are foreseen, as these appear capable of meeting currently known requirements for the future. In recent World Radiocommunication Conferences, however, the spectrum allocated to aeronautical services has been reduced in some bands; in other bands, sharing with non-aeronautical services was adopted notwithstanding strong aviation opposition. As a consequence of these measures, the remaining allocations will need to be fully utilized in order to accommodate the expected traffic growth. Modern technology, better modulation methods and the use of satellites will all contribute to achieve the objective of satisfying demands.

2.3 The introduction of the above-mentioned sharing scenarios must be considered with extreme care. In cases of high operational criticality (such as precision approach and landing), they must be thoroughly proven in real life before the implementation. This may be difficult and risky when expensive satellite systems are being considered and when real-time tests are normally impractical. As a consequence of these difficulties, the international civil aviation community retains the firm opinion that high critical operational systems, such as those used for low visibility approach and landing, should always operate in exclusive frequency bands.

3. ASPECTS ON THE AGENDA FOR WRC-2000

Note.- All of the items appearing in the agenda for WRC-2000 are mentioned below together with a comment. Where the item contains matters of concern to aeronautical radio services, a statement of the ICAO position is also given.

3.1 WRC-2000 Agenda Resolves 1.1 - Requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, in accordance with Resolution 26 (Rev.WRC-97)

3.1.1 Allocations to the aeronautical mobile service and the aeronautical radionavigation service are generally made for all world regions and normally on an exclusive basis. These principles reflect the global process of standardization within ICAO for the promotion of safety and to support the global interoperability of radiocommunication and radionavigation equipment used in transport aircraft. In many cases, country footnotes allocate spectrum to radio services other than those identified in the table of allocations, normally in limited geographical areas. Such allocation can be made on a primary or secondary basis. In circumstances where the country footnote allocation in an aeronautical band is to a service other than the aeronautical, such use generally precludes full and unrestrained use of the band by the aeronautical allocation identified. In highly utilized aviation bands, which have to cope with future increased demands, the presence of country footnotes allocating spectrum to another service is undesirable. In many cases, such practice leads to an inefficient use of available frequencies by both services, notably when the systems have different technical characteristics. For these reasons, the following footnotes should be deleted:

a) **S5.181, S5.197, S5.259**

This family of similar footnotes, covering the bands used for ILS localizer and VOR (108 - 117.975 MHz), glide path (328.6 - 335.4 MHz) and marker beacons (75 MHz), was inserted by the ITU World Administrative Radio Conference 1987 (WARC-87), in the expectation of a release, or reduction, of the use of these bands by the aeronautical radionavigation service. At that time, it was expected, in view of the plans to replace ILS with MLS by 1998, that ILS would be withdrawn. These bands were earmarked by the WARC-87 for re-allocation to the mobile service, in principle for non-aeronautical usage. The plans for replacing ILS with MLS have changed and it is now very unlikely that the mobile service will, in the foreseeable future, be able to get access to these bands. In addition, recently, the need to use the band 108 - 117.975 for global navigation satellite system (GNSS) ground-based augmentation systems (GBAS) has emerged and relevant frequency planning criteria are under development by the GNSS Panel. These country footnotes should now be deleted since they no longer represent a realistic expectation, and additionally create an undesirable precedent for introducing a new service in spectrum that will be used for safety critical operations and will not be vacated in the future; and

b) **S5.355, S5.359**

These footnotes allow the operation of fixed services in the band 1 559 - 1 610 MHz. This band is allocated, on a worldwide basis, to the aeronautical radionavigation service and the radionavigation satellite service and it accommodates various significant elements of the GNSS. Studies undertaken in some Contracting States indicate that a geographical separation exceeding line of sight (in the order of 400 km) is required to ensure safe operation of GNSS. This is a very severe restriction, which will prohibit the use of GNSS over a wide area of the Earth’s surface, including a greater part of Europe, Middle East and Africa. To compensate for these restrictions, retention of terrestrial radionavigation systems may be needed, leading to further inefficient use of available spectrum. More importantly, harmful interference situations can arise leading to disruption to GNSS, affecting the safety of aircraft in flight.

3.1.2 **ICAO POSITION**

3.1.2.1 **To support deletion of footnotes S5.181, S5.197 and S5.259 on the grounds that they no longer represent a realistic possibility to introduce the mobile service in the relevant bands**.

3.1.2.2 **To support deletion of footnotes S5.355 and S5.359 from the band 1 559 - 1 610 MHz, or establish a closing date, not later than 2005, after which the fixed service would cease to operate in this band.**

3.2 **WRC-2000 Agenda Resolves 1.2 - To finalize remaining issues in the review of Appendix S3 to the Radio Regulations with respect to spurious emissions for space services, taking into account Recommendation 66 (Rev.WRC-97) and the decisions of WRC-97 on adoption of new values, due to take effect at a future time, of spurious emissions for space services**

3.2.1 Spurious emission limits for all radio transmitters have been specified in Section 1 of Appendix S3 of the Radio Regulations. Appendix S3 stipulates that these limits will apply to all transmitters installed on or before 1 January 2003 and would include all existing radar transmitters. Conformance with these provisions will require expensive modification. Furthermore, difficulties are expected with the adoption of the method for the measurement of spurious emissions of ATC radar stations.

3.2.2 **ICAO POSITION**

3.2.2.1 **To support measures intended to clarify that radar stations installed on or before 1 January 2003 remain exempt from spurious emission limits.**

3.3 **WRC-2000 Agenda Resolves 1.3 - To consider the results of ITU-R studies in respect of Appendix S7/28 on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services, and take the appropriate decisions to revise this appendix**

3.3.1 No impact on aeronautical radio services has been identified.

3.4 **WRC-2000 Agenda Resolves 1.4 - To consider issues concerning allocations and regulatory aspects related to Resolutions 126 (WRC-97), 128 (WRC-97), 129 (WRC-97), 133 (WRC-97), 134 (WRC-97) and 726 (WRC-97)**

3.4.1 No impact on aeronautical radio services has been identified.

3.5 **WRC-2000 Agenda Resolves 1.5 - To consider regulatory provisions and possible additional frequency allocations for services using high altitude platform stations, taking into account the results of ITU-R studies conducted in response to Resolution 122 (WRC-97)**

3.5.1 No impact on aeronautical radio services has been identified.

3.6 **WRC-2000 Agenda Resolves 1.6.1 - Review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary**

3.6.1 Proposals may be developed aimed at accommodating the mobile service providing the terrestrial elements of IMT-2000 in bands currently allocated to the aeronautical radionavigation and radiolocation service between 2 700 MHz and 3 400 MHz. These bands are heavily used for air traffic control radar surveillance functions and to meet other important national requirements. Some operational functions carried out with these systems cannot be replaced with any other present or expected future system. A full study on the present use of this band by radar stations and on future requirements is necessary to determine whether any removal of these to higher frequency bands is possible. There is no possibility for practical sharing arrangements between these aeronautical radar stations and terrestrial (land) mobile services, hence any proposal of this type is not acceptable.

3.6.1.1 The requirement for airport and TMA primary radar coverage is foreseen to remain. Removal of radar stations from the band 2 700 - 2 900 MHz into the band 2 900 - 3 400 MHz would be extremely difficult if not impossible due to the requirements for large bandwidth for modern radar stations. It would also require major design and reconstruction effort to make the required frequency changes to many radar systems.

3.6.1.2 In the ASIA/PACIFIC region, a number of administrations have indicated that the band 2 700 - 2 900 MHz is the preferred band for primary ATC and airport surveillance radar.

3.6.2 **ICAO POSITION**

3.6.2.1 **To oppose any proposed new allocation to the mobile service, in bands between 2 700 and 3 400 MHz allocated or used by aeronautical services as no compatibility studies have been undertaken yet. Support action for a full study of the present use of these bands by radar stations, and of the feasibility of solutions to allow access by mobile services to provide a basis for an eventual future allocation.**

3.7 **WRC-2000 Agenda Resolves 1.6.2 - Identification of a global radio control channel to facilitate multimode terminal operation and worldwide roaming of IMT-2000**

3.7.1 No impact on aeronautical radio services has been identified.

3.8 **WRC-2000 Agenda Resolves 1.7 - Review of the use of the HF bands by the aeronautical mobile (R) and maritime mobile services with a view to protecting operational, distress and safety communications, taking into account Resolution 346 (WRC-97)**

3.8.1 Resolution 346 addresses the use of specific frequencies by the maritime mobile service in the HF bands allocated to the maritime mobile service.

3.8.2 The aeronautical mobile (R) frequencies of 3 023 kHz and 5 680 kHz are designated for use by aeronautical and maritime services, and by manned space vehicles for search and rescue operations. Furthermore, all frequencies in the HF bands allocated exclusively to the aeronautical mobile (R) service are used to communicate operational safety messages in accordance with RR S43.1. Unauthorized use by other services in contravention of the requirements of the ITU Radio Regulations, and particularly with the provisions of Appendix S27, is increasing and causing serious degradations to safety communications. Special measures to eradicate unauthorized use are therefore necessary.

3.8.3 The frequencies used by the aeronautical mobile (R) service and the conditions for their utilization are contained in Appendix S27 to the ITU Radio Regulations. Conformity with ITU Radio Regulation S1.33 requires only Ccommunications relating to safety and regularity of flight, primarily along national or international civil air routes- to be passed on frequencies assigned to the aeronautical mobile (R) service. In addition, the aeronautical frequencies 3 023 kHz and 5 680 kHz have been designated in S5.115 and in Articles S31 and Appendix S13 for use by ships and aircraft engaged in coordinated search and rescue operations. These uses are ongoing for the foreseeable future.

3.8.4 Presently, HF bands are nearly saturated by the use of analog voice communications. ICAO is implementing a new digital HF data link (HFDL) communications system that will provide a capability for the transfer of air traffic control data to and from pilots operating over oceanic airspace, on polar routes, and in airspace over sparsely populated or developing countries where other communication systems are not practical. The data link communications being implemented worldwide will reduce the burden on voice communications between pilots and controllers by using the data link for routine communications and freeing voice communications for more critical communications. HFDL will not replace voice communications.

3.8.5 **ICAO POSITION**

3.8.5.1 **To support measures that can lead to a removal of all unauthorized use of the frequencies allocated to the aeronautical mobile (R) service between 2 850 and 22 000 kHz.**

3.9 WRC-2000 Agenda Resolves 1.8 - To consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service (FSS) networks in the bands 3 700 - 4 200 MHz and 5 925 - 6 425 MHz, including their coordination with other services allocated in these bands

3.9.1 No impact on aeronautical radio services has been identified.

3.10 WRC-2000 Agenda Resolves 1.9 - To take into account the results of ITU-R studies in evaluating the feasibility of an allocation in the space-to-Earth direction to the mobile-satellite service (MSS) in a portion of the 1 559 - 1 567 MHz frequency range, in response to Resolutions 213 (WRC-97) and 220 (WRC-97)

3.10.1 The band 1 559 - 1 610 MHz is allocated, on a primary basis, to the aeronautical radionavigation service and the radionavigation satellite service. Two GNSS elements, GLONASS and GPS, are currently in operation in this band. The GNSS has been chosen as a core navigation technology of the ICAO CNS/ATM systems. The ICAO GNSS Panel is developing worldwide Standards and Recommended Practices (SARPs) for incorporation in ICAO Annexes. Navigation capability for all types of aircraft for en-route, terminal, precision approach and aerodrome surface operations is envisaged, involving use of the band for augmentation systems such as pseudolites, operating in the band 1 559 - 1 575 MHz and for future satellite navigation systems. As a ground-based emitter, the pseudolite augments the availability of the GNSS by providing an additional ranging signal for the approach phase of flight.

3.10.2 Any sharing of this band with other systems has the potential to cause harmful interference to safety critical aeronautical services and is intrinsically unacceptable. The protection of a radionavigation service requires special treatment under the ITU Radio Regulations, effectively creating a situation of rights to be observed by any other services that may cause harmful interference.

3.10.3 In the case of the GNSS, an array of measures, both administrative and technical, is necessary to assure complete protection at all times. These measures would include adequate coordination and control, enabling immediate remedial action when harmful interference occurs. Technical provisions are an essential part of the protection structure and will require continuation of study in ITU-R and in ICAO, taking account of all the necessary operational features envisaged.

3.10.4 Resolution 220 (WRC-97), which addresses the study on the feasibility of operating a mobile-satellite service (space-to-Earth), includes technical criteria and operational and safety requirements for the aeronautical radionavigation service.

3.10.5 Studies on the feasibility of sharing are being progressed in various fora, including the GNSS Panel. The results indicate that practical and safe sharing conditions cannot be established. In particular, it has been concluded that, in order to protect GNSS systems, MSS space-to-Earth transmissions must be limited to minus 138 dBW/m^2/MHz for wideband signals, and minus 148 dBW/m^2/MHz for narrowband signals. With the current state of the art, MSS systems limited to these low power flux densities are not feasible. Apart from aviation safety considerations, restrictions which constrain the aeronautical use or further development of existing and envisaged systems are not acceptable to aviation.

3.10.6 It is essential to ensure that, in the future, the total band for GNSS (1 559 - 1 610 MHz) remain free from interference from non-aeronautical sources. In particular, no allocation to the mobile-satellite service should be made. Resolution 220 (WRC-97) should be deleted from the Radio Regulations as studies on this issue of sharing GNSS with MSS have concluded that such sharing is not feasible.

3.10.7 **ICAO POSITION**

3.10.7.1 a) **no allocation should be made to the MSS service in the band 1 559 - 1 567 MHz; and**

b) **delete Resolution 220**

3.11 **WRC-2000 Agenda Resolves 1.10 - To consider results of ITU-R studies carried out in accordance with Resolution 218 (WRC-97) and take appropriate action on this subject**

3.11.1 At the WRC-97, strong reservations were expressed by the aeronautical and maritime community on the feasibility of introducing an allocation to the mobile satellite service (generic) in respect of a number of important technical and operational points affecting the aeronautical and maritime mobile-satellite services. Principally, these reservations relate to the need to assure that adequate access to the radio frequency spectrum is available as and when it is needed. Also, concern was expressed with respect to the feasibility of preemption between networks. WRC-97 agreed to a generic allocation to the mobile-satellite service at 1.5/1.6 GHz. Footnote S5.357A was established with the intention of providing access in the future to the AMS(R)S and gives priority to AMS(R)S when coordinating spectrum. There are now serious concerns that footnote S5.357A is ineffective in the situation where all of the allocation is in use, and no release can be agreed. This would appear to negate the intention of the provision, and create the situation of no access as referred to in the ICAO input to WRC-97. Also the introduction of a priority and pre-emption mechanism within and between satellite systems, is becoming questionable. These mechanisms add extra cost and complexity to the systems. This situation must be revisited at WRC-2000 and a more positive mechanism put in place. A number of other aspects of concern to aviation were included in the request to ITU-R study groups to consider and to report to WRC-2000.

3.11.2 The results of ICAO studies of future spectrum requirements are now available. In respect of spectrum estimates, the long-term requirement for AMS(R)S for the various world areas are: 10.8 MHz up to 2 010 and 18 MHz beyond that time frame. These are for safety purposes only and do not include requirements for public correspondence.

3.11.3 The preemption type solution to secure aviation access to the RF spectrum solution has been considered recently in ITU and it has been concluded that this solution is expected to add additional cost and operational complexity in network control systems and network operations, in comparison to systems without full pre-emption capabilities. Further studies on the possibility to provide priority and pre-emption between different services operating within a single system, as well as between systems, are required. Therefore, it is expected that these options might only be implemented in satellite systems in the longer term.

3.11.4 The ITU considered also that the current of capacity planning, where on a regular basis spectrum is reserved for exclusive aeronautical communications, may satisfy the spectrum requirements for AMS(R)S in the near future, due to the low growth rate of AMS(R)S communications. The cooperation of MSS operators is an important element in the process of capacity planning.

3.11.5 There are in aviation considerable doubts on the capability of the present generic allocation to satisfy aeronautical spectrum requirements to meet the future needs of the AMS(R)S.

3.11.6 **ICAO POSITION**

3.11.6.1 **a) to support the spectrum requirements of 10.8 MHz up to 2 010 and 18 MHz beyond 2010;**

b) to recover the exclusive allocation of the bands 1 545 - 1 555 MHz and 1 646.5 - 1 656.5 MHz to AMS(R)S, unless

c) adequate technical and regulatory provisions are agreed to:

1) guarantee the availability of spectrum for aeronautical communications as required; and

2) ensure that aeronautical communications in Categories 1 to 6 of Article S.44 are given priority and immediate access at all times.

3.12 **WRC-2000 Agenda Resolves 1.11 - To consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions 214 (Rev.WRC-97) and 219 (WRC-97)**

3.12.1 The spectrum below 1 GHz contains a number of important aeronautical and radionavigation bands, where the main aeronautical terrestrial radio services supporting air operations are located. All of these bands are under considerable pressure to provide for the future growth of air traffic in the years ahead.

3.12.2 The main VHF communications band at 117.975 - 137 MHz supports all of the short- and medium-range communications over continental airspace and will continue for the foreseeable future to provide this function. Radionavigation systems operate at 75 MHz, 108 to 117 975 MHz, 324.6 to 335.4 MHz, and 960 to 1 215 MHz. They will be required well into the next century.

3.12.3 **ICAO POSITION**

3.12.3.1 **Maintain all aeronautical allocations below 1 GHz without change and taking account of the ICAO position on Agenda Item 1.1 in regard to S5.181, S5.197 and S5.259.**

3.13 **WRC-2000 Agenda Resolves 1.12 - To consider the progress of studies on sharing between feeder links of non-GSO MSS networks and GSO FSS networks in the bands 19.3 - 19.7 GHz and 29.1 - 29.5 GHz, taking into account Resolution 121 (Rev.WRC-97)**

3.13.1 No impact on aeronautical radio services has been identified.

3.14 **WRC-2000 Agenda Resolves 1.13.1 - To review and, if appropriate, revise the power limits appearing in Articles S21 and S22 in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services**

3.14.1 No impact on aeronautical radio services has been identified.

3.15 **WRC-2000 Agenda Resolves 1.13.2 - To consider the inclusion in other frequency bands of similar limits in Articles S21 and S22, or other regulatory approaches to be applied in relation to sharing situations**

3.15.1 No impact on aeronautical radio services has been identified.

3.16 WRC-2000 Agenda Resolves 1.14 - To review the results of the studies on the feasibility of implementing non-GSO MSS feeder links in the 15.43 - 15.63 GHz in accordance with Resolution 123 (WRC-97)

3.16.1 The report of CPM-97 to WRC-97 proposed a sharing methodology between the aeronautical radionavigation systems presently in operation in this band, and the proposed Earth-to-space and space-to-Earth transmissions of the fixed-satellite service in the same band. Although international civil aviation had to accept the present allocation in Article S5, together with the safeguards for both services contained in the relevant ITU-R Resolutions, as a basis for sharing, it should be noted that this has been achieved by placing restrictions on several radionavigation systems, both ground-based and onboard aircraft.

3.16.2 The submission to WRC-97 for the FSS allocation mentioned the limited nature of the requirement. Aviation is advised that changes to these plans have now taken place. Also the constraints on the FSS placed by the WRC-97 further limit the use of this band by the FSS. In the interest of spectrum efficiency, it is argued that the allocation to the fixed-satellite service should be removed if it is anticipated that the allocation will not in fact be used. It is further proposed that any limited use should be covered by a footnote.

3.16.3 **ICAO POSITION**

3.16.3.1 **No further restrictions to the aeronautical radionavigation service are acceptable. Support action for removal of the fixed-satellite service, in particular, if under the current conditions the band cannot be efficiently used by the fixed-satellite service.**

3.16.3.2 **Support limitation to the footnote allocation to the FSS indicating that the band is used for the fixed satellite service and that no more assignments should be made to the FSS after the closure date of the WRC-2000.**

3.17 WRC-2000 Agenda Resolves 1.15.1 - To consider new allocations to the radionavigation-satellite service in the range from 1 GHz to 6 GHz required to support developments

3.17.1 The allocation to the radionavigation service in the band 1 559 - 1 610 MHz supports operations of GLONASS and GPS, the two radionavigation satellite systems which, together with supporting augmentation systems, are the presently identified elements of the ICAO GNSS system. The availability of adequate spectrum to support second generation systems or to enhance the current use of GNSS is fully supported. Due account must be given to the effect of additional allocations on the current usage of frequency bands where additional RNSS allocations are proposed. No requirements are foreseen for RNSS systems in the band above 5 GHz. With respect to the possible use of the band 1 164 - 1 188 MHz by an additional GNSS frequency, ICAO is considering compatibility aspects to secure protection of the current aeronautical users of this band.

3.17.2 Support the availability of adequate spectrum for GNSS systems taking into account the result of studies assessing the compatibility between RNSS and the current allocation to the band being considered. Protection needs to be given to ensure that current users of the band are not affected by these allocations.

3.17.3 **ICAO POSITION**

3.17.3.1 **To support the availability of adequate spectrum for GNSS systems.**

3.18 **WRC-2000 Agenda Resolves 1.15.2 - To consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the bands 1 215 - 1 260 MHz and 1 559 - 1 610 MHz**

3.18.1 Introduction of an allocation enabling space-to-space operations of GLONASS and GPS does not affect aviation. As such allocation will not interfere with the projected aeronautical use of GNSS, proposals for this allocation can be permitted.

3.18.2 **ICAO POSITION**

3.18.2.1 **No objections to a space-to-space allocation to the radionavigation satellite service in the bands 1 215 - 1 260 MHz and 1 559 - 1 610 MHz.**

3.19 **WRC-2000 Agenda Resolves 1.15.3 - To consider the status of allocations to services other than the radionavigation-satellite service (Nos. S5.355 and S5.359) in the band 1 559 - 1 610 MHz**

3.19.1 For more information on this subject, see paragraph 3.11.

3.19.2 **ICAO POSITION**

3.19.2.1 **The operation of fixed service on the frequencies between 1 559 and 1 610 MHz should be discouraged and ceased.**

3.20 **WRC-2000 Agenda Resolves 1.16 - To consider allocation of frequency bands above 71 GHz to the earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution 723 (WRC-97)**

3.20.1 No impact on aeronautical radio services has been identified.

3.21 **WRC-2000 Agenda Resolves 1.17 - To consider possible worldwide allocation for the earth exploration-satellite (passive) and space research (passive) services in the band 18.6 - 18.8 GHz, taking into account the results of the ITU-R studies**

3.21.1 No impact on aeronautical radio services has been identified.

3.22 **WRC-2000 Agenda Resolves 1.18 - To consider the use of new digital technology for the maritime mobile service in the band 156 - 174 MHz and consequential revision of Appendix 18/S18, taking into account Resolution 342 (WRC-97)**

3.22.1 No impact on aeronautical radio services has been identified.

3.23 **WRC-2000 Agenda Resolves 1.19 - To consider the report of the inter-conference representative group (IRG) submitted by the Director of the Radiocommunication Bureau and determine the basis for replanning by the next conference so as to afford each country an amount of spectrum that permits the economical development of a broadcasting-satellite service system**

3.23.1 No impact on aeronautical radio services has been identified.

3.24 **WRC-2000 Agenda Resolves 1.19 bis - In accordance with Article S14, to consider objections expressed by administrations with respect to the Radio Regulations Board’s Rules of Procedure relating to the application of RR 2674/S23.13 in order for the Bureau to modify its findings in accordance with the conclusions of the Conference**

3.24.1 No impact on aeronautical radio services has been identified.

3.25 **WRC-2000 Agenda Resolves 1.20 - To consider the issues related to the application of Nos. S9.8, S9.9 and S9.17 and the corresponding parts of Appendix S5 with respect to Appendices S30 and S30A, with a view to possible deletion of Articles 6 and 7 of Appendices S30 and S30A, also taking into consideration Recommendation 35 (WRC-95)**

3.25.1 No impact on aeronautical radio services has been identified.

3.26 **WRC-2000 Agenda Resolves 1.21 - To consider the report from the Radiocommunication Bureau on results of the analysis in accordance with Resolution 53 (WRC-97) and take appropriate actions**

3.26.1 No items have been identified at this point in time.

3.27 **WRC-2000 Agenda Resolves 2 - To examine the revised ITU-R recommendations 28 (WRC-95); and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution 27 (Rev.WRC-97)**

3.27.1 At this point, no ITU-R recommendations referring exclusively to aeronautical radio services and incorporated by reference in the ITU Radio Regulations have been identified.

3.27.2 Provision RR S34.1 of the ITU Radio Regulations specifies that ELT signals on 406.0 MHz or in the band 1 645.5 - 1 646.5 MHz shall be in accordance with relevant ITU-R Recommendations (see Resolution 27 (WRC-95)).

3.27.3 **ICAO POSITION**

3.27.3.1 **To support the policy of linked reference in respect of RR S34.1 for ELTs.**

3.28 **WRC-2000 Agenda Resolves 3 - To consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference**

3.28.1 No items have been identified at this point in time.

3.29 **WRC-2000 Agenda Resolves 4 - In accordance with Resolution 95 (WRC-97), to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation**

3.29.1 No items have been identified at this time.

3.30 **WRC-2000 Agenda Resolves 5 - To review, and take appropriate action on, the report from the Radiocommunication Assembly submitted in accordance with Nos. 135 and 136 of the Convention (Geneva, 1992)**

3.30.1 To be addressed when the further material is available.

3.31 **WRC-2000 Agenda Resolves 6 - To identify those items requiring urgent action by the radiocommunication study groups in preparation for the next world radiocommunication conference**

3.31.1 No items have been identified at this point in time.

3.32 WRC-2000 Agenda Resolves 7.1 - To consider and approve the report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-97

3.32.1 No items have been identified at this point in time.

3.33 WRC-2000 Agenda Resolves 7.2 - To recommend to the Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent Conference and on possible agenda items for future conferences

3.33.1 No items for inclusion in the agenda for the next WRC have been identified.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Document 5-E
25 January 2000
Original: English

PLENARY MEETING

Note by the Secretary-General

INFORMATION ON THE OCCUPANCY BY THE FIXED AND MOBILE SERVICES IN THE ADDITIONAL HF BANDS ALLOCATED BY WARC-92 TO THE BROADCASTING SERVICES

This document contains the report of the Director of the Radiocommunication Bureau which was prepared in response to Resolution 29 (WRC-97).

Yoshio UTSUMI
Secretary-General

Annex: 1

ANNEX

Director, Radiocommunication Bureau

REPORT ON THE ISSUES REFERRED TO IN RESOLUTION 29 (WRC-97)

1 Introduction

By its Resolution 29, WRC-97 resolved to instruct the Director, BR,

> *"1 to present a report to the 1999 Conference Preparatory Meeting (CPM-99) and WRC-99, providing information gathered by means of consultation with administrations, on the occupancy by fixed and mobile services in each of the additional HF bands allocated by WARC-92 to the broadcasting service;*
>
> *2 to provide to CPM-99 and WRC-99 any new information with regard to possible sharing between broadcasting and other services in the HF bands, together with the information already provided to WARC-92".*

An interim report on these subjects was presented to CPM-99. Following that meeting, the Bureau updated the information on the occupancy by the fixed and mobile services in the bands referred to in No. S5.134 (Section 2 of this report). Section 3 of this report, including the associated attachments, which deal with information on the possible sharing between broadcasting and other services in the HF bands, is identical with the information already presented to CPM-99.

2 Information on the occupancy by the fixed and mobile services in some HF bands

In April 1999, the Radiocommunication Bureau initiated the consultation procedure referred to in *resolves 1* of Resolution 29 (WRC-97). A questionnaire was addressed to all ITU Member States and the administrations were requested to indicate the current use of the frequency bands referred to in No. **S5.134**, which were allocated to the broadcasting service by WARC-92 and which would become available for the broadcasting service on 1 April 2007, as indicated in provision Nos. **S5.136**, **S5.143**, **S5.146** and **S5.151**. In a parallel activity, the Bureau sent extracts from the Master Register to 166 administrations that have recorded frequency assignments to the fixed and mobile services in the bands subject to consultation and asked them to review the extracts with a view to update the information recorded in the Master Register.

By 2 December 1999, 66 administrations replied to the questionnaire. The summary of these replies is given in Table 1, for each specific band. The symbols used in Table 1 are explained in the auxiliary Table which follows Table 1.

TABLE 1

Current and intended occupancy of some HF bands by fixed and mobile services (as indicated by administrations)

Frequency band (kHz)	XX	U2	U5	U7	UU
5 900-5 950	BTN, CBG, CVA, EST, FIN, HRV, ISL, ISR, LTU, MKD, MNG, MWI, POL, SUI, TON	DNK, ERI, TJK, UZB,	ARM, MOZ, TZA,	B, BEL, BLR, D, ETH, J, KOR, LBY, LSO, NCG, S, THA, YEM	ARG, AUS, AUT, BDI, BFA, BGD, BOT, CAN, CHN, EGY, GHA, GNE, HNG, IND, IRN, MLD, MLI, MRC, NMB, SLV, TUR, UAE, UKR, USA, VTN, ZMB

Symbol	Meaning
XX	This band is not used for the fixed and mobile services and there are no intentions for such an use
U2	This band is currently used for the fixed and mobile services; however, there are no intentions for such a use ***after 1 January 2002***
U5	This band is currently used for the fixed and mobile services; however, there are no intentions for such a use ***after 1 January 2005***
U7	This band is currently used for the fixed and mobile services; however, there are no intentions for such a use ***after 1 January 2007***
UU	This band is currently used for the fixed and mobile services and there are intentions for such a use ***beyond 1 January 2007***

In a parallel activity, several administrations updated the information in the Master Register on their frequency assignments to stations in the fixed and mobile services in the bands which were subject to consultation. In general, this action resulted in a deletion of the unused assignments from the Master Register, although several administrations notified new frequency assignments. The comparative situation of the number of frequency assignments, in each of the bands referred to in No. **S5.134**, before the consultation procedure (on 1 April 1999), at the time of preparation of the interim report to CPM-99 (6 September 1999) and at the time of preparation of this report (2 December 1999) is given in Table 2.

TABLE 2

Occupancy of some HF bands (situation in the MIFR)

Frequency band (kHz)	**No. of assignments (1.4.99)**	**No. of assignments (6.9.99)**	**No. of assignments (2.12.99)**

3 Information on possible sharing between broadcasting and other services in the HF bands

3.1 General considerations

The CCIR Report to WARC-92 in its Section 5 (see *Attachment 1* to this document) deals with compatibility considerations arising from the allocation of spectrum to HF broadcasting. Work carried out since 1992 on this subject has not significantly modified the above-mentioned considerations. The following sections indicate changes and updates in the ITU-R texts relevant to sharing between broadcasting and other services in the HF bands.

3.2 Status of the work

Since WARC-92 results of studies on sharing have been included in the following revised texts:

a) Recommendation ITU-R F.240-6 (Signal-to-interference protection ratios for various classes of emission in the fixed service below about 30 MHz): Table 1 to this Recommendation (see *Attachment 2* to this document) has been updated and complemented. The CCIR Report to WARC-92 indicated this text as the most suitable to provide a satisfactory set of protection criteria applicable to sharing of frequencies by fixed and mobile stations.

b) Recommendation ITU-R BS.560-4 (Radio-frequency protection ratios in LF, MF and HF broadcasting): Annex 4 to this Recommendation has been updated to include the planning parameters adopted by HFBC-87.

c) Recommendation ITU-R BS.640-3 (Single-sideband (SSB) system for HF broadcasting): The text includes now an improved specification of the suppression of the unwanted sideband and the noise-limited sensitivity of SSB receivers.

d) Recommendation ITU-R P.1060 (Propagation factors affecting frequency sharing in HF terrestrial systems): This text identifies the propagation factors and conditions that may facilitate sharing in the HF bands.

e) Recommendation ITU-R M.831 (Frequency sharing between services in the band 4-30 MHz): This text refers to sharing between fixed, mobile and broadcasting services at HF. It includes a list of technical and operational characteristics pertinent to the various services which should be taken into account when defining sharing criteria.

An updated list of related ITU-R texts is to be found in *Attachment 3*.

It should be finally noted that an increasing activity is now addressed to the development of digital sound broadcasting systems operating at frequencies below 30 MHz, in the framework of ITU-R Q.217-1/10. It is anticipated that the implementation of such systems will facilitate sharing with other services. A recommendation concerning such systems is foreseen during the year 2000.

5 Compatibility considerations arising from the allocation of spectrum to HF broadcasting

(Resolves 2.2.2 of Resolution No. 995 of the ITU Administrative Council)

5.1 General considerations

The agenda of the WARC-92 calls for the possible extension of the frequency spectrum allocated exclusively to HF broadcasting, as indicated in Recommendation 511 (HFBC-87)[2]. This may extend the HF broadcasting allocations into spectrum at present allocated to other services. Existing assignments would need to be displaced to make room for the new broadcasting allocations. This displacement of existing assignments to other parts of the spectrum should be organized in an orderly manner and should not harmfully affect the quality of operations for the stations concerned. The implementation of techniques such as reduced carrier single-sideband modulation for the HF broadcasting service should be considered in the interests of enhanced spectrum efficiency and access to the HF bands.

5.2 Sharing considerations service-by-service

5.2.1 Amateur and amateur-satellite services

Sharing arrangements exist now between the amateur service and:

– the amateur-satellite service, in exclusive amateur and amateur-satellite service HF bands;

– the fixed service in six bands (3.5, 7, 10.1, 14.25, 18.068 and 24.89 MHz);

– the mobile services in two bands (3.5 and 24.89 MHz);

– the meteorological aids service (24.89 MHz).

The amateur-satellite service can only share the HF bands with the amateur service and, under certain circumstances, with the meteorological aids service.

Reason – low signal level service.

The sharing of frequency bands by the amateur and broadcasting services is undesirable and should be avoided.

Reason – system incompatibility between broadcasting and amateur services.
(See RR Resolution 641 (Rev. HFBC-87)).

[1] In order to facilitate the reading of this Attachment, the Bureau introduced also the new references to the provisions of Radio Regulations, as they appear in the 1998 edition of the RR.

[2] Note by the Bureau: this Recommendation was suppressed by WARC-92.

5.2.2 Standard frequency and time signal service

This service cannot share on an equal basis with any other service. It has a primary status in currently assigned bands (5, 10, 15, 20 and 25 MHz). It accepts the space research service on a secondary basis.

Reason – standard frequency and time service signals operate in narrow frequency bands and are used on a high priority basis by all other services; therefore they require a high degree of protection.

5.2.3 Space research

This service operates on a secondary basis in the bands (5, 10, 15, 20 and 25 MHz) designated for primary use by the standard frequency and time signals service.

5.2.4 Radioastronomy

This service cannot share the HF band with any other service except after special coordination or procedures (13.36 and 25.55 MHz, No. **S5.149**/RR533, 545).

Reason – service operates at extremely low signal levels (near or below noise level).

5.2.5 Meteorological aids

This service is now sharing at 27.5 MHz with mobile and fixed services. Under some circumstances it can also share with the amateur and amateur-satellite services (24.89 MHz).

Reason – existing sharing situation with mobile and fixed services. Sharing with the amateur service is possible where meteorological aids do not operate continuously.

5.2.6 Aeronautical mobile (R)

This service cannot share with other services within a Region.

Reason – contains safety of life communications.

5.2.7 Aeronautical mobile (OR)

Below 6 MHz, this service is now sharing with land mobile, maritime mobile (except international distress and calling frequencies), fixed, amateur services, with tropical broadcasting and with ISM applications.

Above 6 MHz, this service operates to a Plan and cannot share with other services.

Reason – contains safety of life communications.

5.2.8 Maritime mobile

Maritime mobile international distress and calling frequencies cannot be shared with other services except for search and rescue operations (e.g., concerning manned space vehicles).

Reason – contains safety of life communications.

Below 4 063 kHz, the maritime mobile service (except international distress and calling frequencies) is now sharing with the land mobile, fixed, and amateur services, with tropical broadcasting and with ISM applications.

Above 4 063 kHz, this service operates to a Plan[3] and does not share with any other service except fixed in the band 8 100 to 8 195 kHz.

Reason – contains safety of life communications.

5.2.9 Land mobile

This service is now sharing with the maritime (except international calling and distress frequencies), fixed and amateur services, with tropical broadcasting below 6 MHz (but see § 5.7), and with ISM applications.

5.2.10 Fixed

This service is now sharing with the land mobile, maritime mobile (except international calling and distress frequencies) and amateur services, with tropical broadcasting below 6 MHz (but see § 5.7), and with ISM applications. Some sharing with the broadcasting service has been adopted within the broadcasting band extensions agreed by WARC-79. (See **S5.147**/RR 530).

5.2.11 ISM applications

These applications are now sharing relatively narrow HF bands with the land mobile and fixed services subject to special authorization by the administration concerned or provided that radiocommunication services operating within the band accept harmful interference which may be caused by these applications. (See **S5.138**/RR 524 and **S5.150**/RR 534, 546.)

5.3 Protection ratios

Sharing is facilitated by choice of a protection ratio less than that for the highest quality, e.g., use of a ratio that produces a median or acceptable quality.

Protection criteria related to sharing of frequencies by fixed stations are contained within CCIR Recommendation 240. Although it was developed for use by the fixed service only, this Recommendation has also been found useful for the mobile services. CCIR Recommendation 240 provides the most current and satisfactory set of protection criteria applicable to this sharing problem.

Protection ratios relative to some sharing situations are given in Table V-I which has been taken from CCIR Recommendation 240. The Table contains a choice of three protection ratio values, relating to different quality grades for telephony services only.

[3] Note by the Bureau: as a matter of fact, only some sub-bands are subject to a Plan, notably those parts that are reserved for duplex radiotelephony, see Appendix S25 to the RR.

TABLE V-I - Minimum required protection ratios in dB

Class of emission of wanted signal		Class of emission of interfering signal																		
		A1A	A1B (1) 50 baud	A1B 100 baud	A2A A2B	F1B (1)	F7B	R3C	F3C	A3E (5) (7) (9)	H3E (7)	R3E (7)	J3E (7)	B8E (7)	J2B	H2A H2B	J7B	R7B	(15) non-diversity	(15) diversity

R7B			18.5			21.5	21.5								18.5	12.5				

( ) : See notes on next page.

Notes to Table V-I:

(1) Bandwidth of interfering signals limited to 500 Hz.

(2) For a probability of character error $P_c = 0.0001$.

(3) For a probability of character error $P_c = 0.001$.

(4) For a traffic efficiency of 90%.

(5) For telephony the values of protection ratios for stable conditions have been derived from information contained in Report 989 and 990. The figures for A3E telephony are valid only for reception with an SSB receiver.

(6) With the use of a noise reducer for the wanted signal, the figures in column 1 are reduced by ... dB (to be determined).

(7) With the use of Lincompex terminals for the wanted signal, the figures in column 1 are reduced by ... dB (to be determined). When the interfering signal is a telephony transmission using Lincompex terminals, the figures in column 1 are increased by ... dB (to be determined).

(8) Values derived from information contained in Report 991.

(9) Average degree of modulation 70%; sideband components extended to ± 3 kHz.

(10) Combined allowances for fading safety factor and intensity fluctuation factor.

(11) The probability distribution of the radio of two signals fading independently has been applied in accordance with Doc. [CCIR, 1953]. The combined intensity fluctuation allowance for two signals has been taken as 7 dB, which represents a compromise between the 0 dB allowance, appropriate to perfectly correlated intensity fluctuations of the two signals, and the 14 dB allowance appropriate to uncorrelated intensity fluctuations of the two signals.

(12) For protection 99.99% of the time.

(13) Based on 90% traffic efficiency.

(14) Based on 90% protection.

(15) Provisional total fading allowances (10) for the protection of a fading signal against an interfering signal subject to fading and day-to-day intensity fluctuations. (See (11)). (dB to be added to values in columns).

(16) JU: just usable; MC: marginally commercial; GC: good commercial.

5.4 Dynamic frequency sharing

Dynamic frequency sharing or real time frequency management is a useful tool for providing communication circuits that are not otherwise possible because of interference constraints. Dynamic sharing implies operation on a secondary basis where there is no possibility of a claim for interference-free communication. This type of sharing is possible with frequency-agile transmitting and receiving equipment made feasible by modern technology. Dynamic frequency sharing is enhanced when one service operates with high power on known or published frequencies, such as the broadcasting service and the dynamic service operates with low power involving two-way communications such as in the fixed, mobile and amateur services. No. **S5.147**/RR 530 gives an example of bands in which dynamic sharing is possible.

5.5 Noise

Using the most accurate noise data will facilitate prudent management and efficient utilization of the frequency spectrum. The use of data on radio noise is addressed in CCIR Recommendation 372.

5.6 Encouraging the introduction of single-sideband (SSB) modulation

The use of SSB in the HF bands allocated to the broadcasting service will reduce overall interference levels and contribute to HF spectrum efficiency. Implementation of SSB in accordance with Appendix **S11**/45 to the Radio Regulations should, therefore, be encouraged. Consideration should also be given to limiting HF broadcasting to reduced carrier SSB, initially in any band extensions agreed at the WARC-92 as this would maximize spectrum efficiency. As new HF transmitters currently being installed are capable of SSB operation, the emphasis should be on early manufacture and sale of low-cost receivers and consideration should be given to advancing the date of the final transition to SSB and cessation of HF double-sideband broadcasting.

5.7 Existing undesirable compatibility situations

There are some existing sharing situations which have been found in practice to create unacceptable levels of interference under certain conditions.

5.7.1 Amateur and broadcasting services

The 7 100-7 300 kHz band is allocated exclusively to the broadcasting service in Regions 1 and 3 and exclusively to the amateur service in Region 2. In general this geographical sharing works despite the large disparity in signal levels between the two services. However, during periods of good propagation between Regions 1 and 2, the broadcasting transmissions can produce signal strengths in Region 2 sufficiently high to cause serious interference to the sensitive receivers used in the amateur service. The degree of interference experienced in Region 2 varies with time-of-day, season, solar activity and distance from Region 1.

5.7.2 Broadcasting and fixed services

Below 6 MHz, the broadcasting and fixed services are allocated to the same frequency bands in some parts of the HF spectrum. In general, a narrow-bandwidth fixed service transmission can operate successfully within the service area of a normal-bandwidth broadcasting signal provided the fixed service transmission is not coincident with the broadcasting carrier. However, if such a fixed service is a continuous transmission, it can seriously degrade the reception of the broadcasting transmission by producing a heterodyne whistle in the broadcasting receiver.

5.8 Band adjacency

In any discussions regarding band extensions for HF broadcasting, account should be taken of the provisions of No. **S4.5**/RR 343.

5.9 Channel adjacency

Any HF spectrum re-allocation should take into account, where appropriate, the differing power-levels of adjacent channel services.

								17.5				11.5																	
								18.5				12.5																	

Notes to Table 1:

* Under “class of emission”, *B* represents the receiver bandwidth and 2*D* represents the total frequency shift.

(1) Bandwidth of interfering signals limited to 500 Hz.

(2) For a probability of character error $P_c = 0.0001$.

(3) For a probability of character error $P_c = 0.001$.

(4) For a traffic efficiency of 90%.

(5) For telephony the values of protection ratios for stable conditions have been derived from information contained in Annexes 1 and 2. The figures for A3E telephony are valid only for reception with an SSB receiver.

(6) With the use of a noise reducer for the wanted signal, the figures in column 1 are reduced by ... dB (to be determined).

(7) With the use of Lincompex terminals for the wanted signal, the figures in column 1 are reduced by ... dB (to be determined). When the interfering signal is a telephony transmission using Lincompex terminals, the figures in column 1 are increased by ... dB (to be determined).

(8) Values derived from information contained in Annex 3.

(9) Average degree of modulation 70%; sideband components extended to ± 3 kHz.

(10) Combined allowances for fading safety factor and intensity fluctuation factor.

(11) The probability distribution of the radio of two signals fading independently has been applied. The combined intensity fluctuation allowance for two signals has been taken as 7 dB, which represents a compromise between the 0 dB allowance, appropriate to perfectly correlated intensity fluctuations of the two signals, and the 14 dB allowance appropriate to uncorrelated intensity fluctuations of the two signals.

(12) For protection 99.99% of the time.

(13) Based on 90% traffic efficiency.

(14) Based on 90% protection.

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Document 6-E*[*]
10 January 2000
Original: English

PLENARY MEETING

Saudi Arabia (Kingdom of)

PROPOSAL FOR THE WORK OF THE CONFERENCE

The Administration of Saudi Arabia carefully considered the various agenda items for the World Radiocommunication Conference (Istanbul, 2000). The proposals of Saudi Arabia relating to various agenda items will be presented to the Conference. However, a proposal related to one agenda item is included in this document for consideration by the Conference. The proposed modification is based on pressing service demands on the national level.

Agenda item 1.1

MOD ARS/6/1

S5.316 *Additional allocation*: in Germany, Saudi Arabia, Bosnia and Herzegovina, Burkina Faso, Cameroon, Côte d'Ivoire, Croatia, Denmark, Egypt, Finland, Israel, Kenya, the Former Yugoslav Republic of Macedonia, Libya, Liechtenstein, Monaco, Norway, the Netherlands, Portugal, Syria, Sweden, Switzerland and Yugoslavia, the band 790-830 MHz, and in these same countries and in Spain, France, Gabon and Malta, the band 830-862 MHz, are also allocated to the mobile, except aeronautical mobile, service on a primary basis. However, stations of the mobile service in the countries mentioned in connection with each band referred to in this footnote shall not cause harmful interference to, or claim protection from, stations of services operating in accordance with the Table in countries other than those mentioned in connection with the band.

---

[*] Pursuant to Resolution 26 (Rev.WRC-97), the secretariat notes that this contribution was received on 4 January 2000.

PLENARY MEETING

Estonia (Republic of)

PROPOSAL FOR WORK OF THE CONFERENCE

The Republic of Estonia would like to make the following proposal for the work of the World Radiocommunication Conference (Istanbul, 2000) under agenda item 1.1 with respect to a footnote contained in Article S5:

MOD EST/7/1

S5.262 *Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, Bulgaria, Colombia, Costa Rica, Cuba, Egypt, the United Arab Emirates, Ecuador, ~~Estonia,~~ Georgia, Hungary, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kazakstan, Kuwait, Liberia, Malaysia, Moldova, Nigeria, Uzbekistan, Pakistan, the Philippines, Qatar, Syria, Kyrgyzstan, Slovakia, Romania, Russian Federation, Singapore, Somalia, Sri Lanka, Tajikistan, Turkmenistan, Ukraine and Yugoslavia, the band 400.05-401 MHz is also allocated to the fixed and mobile services on a primary basis.

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

Czech Republic

PROPOSALS FOR THE WORK OF THE CONFERENCE

AGENDA ITEM 1.1

Introduction

Item 1.1 of the Conference agenda refers to the deletion of country names from the footnotes to the Table of Frequency Allocations in cases where the corresponding allocations are no longer required.

The Czech Republic submits the following proposals for deletion of its country name from the footnotes indicated below, based on the text of the Radio Regulations adopted by the World Radiocommunication Conference (Geneva, 1997).

MOD CZE/8/1

S5.290 *Different category of service:* in Afghanistan, Armenia, Azerbaijan, Belarus, China, Japan, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia~~, the Czech Republic,~~ Russian Federation, Tajikistan, Turkmenistan and Ukraine, the allocation of the band 460-470 MHz to the meteorological-satellite service (space-to-Earth) is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21**.

MOD CZE/8/2

S5.387 *Additional allocation:* in Armenia, Azerbaijan, Belarus, Georgia, Kazakstan, Mali, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia,~~ the Czech Republic,~~ Romania, Russian Federation, Tajikistan, Turkmenistan and Ukraine, the band 1 770-1 790 MHz is also allocated to the meteorological-satellite service on a primary basis, subject to agreement obtained under No. **S9.21**.

MOD CZE/8/3

S5.521 *Alternative allocation:* in Germany, Denmark, the United Arab Emirates, Greece~~,~~ and Slovakia~~ and the Czech Republic~~, the band 18.1-18.4 GHz is allocated to the fixed, fixed-satellite (space-to-Earth) and mobile services on a primary basis (see No. **S5.33**). The provisions of No. **S5.519** also apply.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

Pakistan (Islamic Republic of)

PROPOSALS FOR THE WORK OF THE CONFERENCE

The Administration of Pakistan wishes to make the following proposals for the work of the Conference:

MOD PAK/9/1

S5.65 *Different category of service:* in Bangladesh~~,~~ and the Islamic Republic of Iran ~~and Pakistan~~, the allocation of the bands 112-117.6 kHz and 126-129 kHz to the fixed and maritime mobile services is on a primary basis (see No. **S5.33**).

MOD PAK/9/2

S5.277 *Additional allocation:* in Angola, Armenia, Azerbaijan, Belarus, Cameroon, the Congo, Djibouti, Gabon, Georgia, Hungary, Kazakstan, Latvia, Mali, Moldova, Mongolia, Uzbekistan, ~~Pakistan,~~ Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Rwanda, Tajikistan, Chad, Turkmenistan and Ukraine, the band 430-440 MHz is also allocated to the fixed service on a primary basis.

MOD PAK/9/3

S5.331 *Additional allocation:* in Algeria, Germany, Austria, Bahrain, Belgium, Benin, Bosnia and Herzegovina, Burundi, Cameroon, China, Croatia, Denmark, the United Arab Emirates, France, Greece, India, the Islamic Republic of Iran, Iraq, Kenya, The Former Yugoslav Republic of Macedonia, Liechtenstein, Luxembourg, Mali, Mauritania, Norway, Oman, ~~Pakistan,~~ the Netherlands, Portugal, Qatar, Senegal, Slovenia, Somalia, Sudan, Sri Lanka, Sweden, Switzerland, Turkey and Yugoslavia, the band 1 215-1 300 MHz is also allocated to the radionavigation service on a primary basis.

MOD PAK/9/4

S5.483 *Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, China, Colombia, the Republic of Korea, Costa Rica, Egypt, the United Arab Emirates, Georgia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kazakstan, Kuwait, Latvia, Lebanon, Moldova, Mongolia, Uzbekistan, ~~Pakistan,~~ Qatar, Kyrgyzstan, Democratic People's Republic of Korea, Romania, Russian Federation, Tajikistan, Turkmenistan, Ukraine, Yemen and Yugoslavia, the band 10.68-10.7 GHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis. Such use is limited to equipment in operation by 1 January 1985.

MOD PAK/9/5

S5.509 *Additional allocation:* in Japan ~~and Pakistan~~ the band 14.25-14.3 GHz is also allocated to the mobile, except aeronautical mobile, service on a primary basis.

ISTANBUL, 8 MAY – 2 JUNE 2000

WORKING GROUP 2 OF THE PLENARY

United States of America

PROPOSALS FOR AGENDA ITEM 7.2

TO RECOMMEND TO COUNCIL ITEMS FOR INCLUSION IN THE AGENDA FOR THE NEXT WRC, AND TO GIVE ITS VIEWS ON THE PRELIMINARY AGENDA FOR THE SUBSEQUENT CONFERENCE AND ON POSSIBLE AGENDA ITEMS FOR FUTURE CONFERENCES

Proposal for the agenda for the 2003 World Radiocommunication Conference

Please add *resolves* 2.14 through 2.16 to Resolution [WRC-03].

ADD USA/12/311

resolves

2.14 to consider additional allocations on a worldwide basis for the non-GSO MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to MOD Resolution **214 (Rev.WRC-2000)**;

2.15 to consider additional allocations in the bands near 1.4 GHz for the non-GSO MSS with service links below 1 GHz, taking into account the results of ITU-R studies conducted in response to MOD Resolution **127 (Rev.WRC-2000)**;

2.16 to consider primary allocations between 10 and 30 GHz for the space research service (space-to-Earth) to accommodate wideband downlink requirements;

Reasons: Draft resolution for the next WRC.

Proposal for the preliminary agenda for the 2005/6 World Radiocommunication Conference

In Resolution [WRC-05/06], please replace *resolves* 2.2 and renumber 2.2.3 to 2.3 and replace with the following text:

MOD USA/12/312

2.2 to review studies related to allocations to the non-GSO MSS below 1 GHz in the 470-862 MHz band (Resolution **728 (WRC-97)**);

2.3 to review studies and consider allocations if appropriate to the non-GSO MSS below 1 GHz in the 405-406 MHz band (Resolution **219 (WRC-97)**);

Add *resolves* 2.4 to Resolution [WRC-05/06].

ADD USA/12/313

2.4 to review studies and consider allocations in the frequency bands above approximately 3 000 GHz;

Reasons: Draft resolution for the next-but-one WRC.

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROPOSALS FOR AGENDA ITEM 7.2

to recommend to Council items for inclusion in the agenda for the next WRC, and to give its views on the preliminary agenda for the subsequent conference and on possible agenda items for future conferences

1 Proposal for the agenda for the 2003 World Radiocommunication Conference

Background information

The United States proposal for the agenda of WRC-03 is contained in Resolution [WRC-03].

ADD USA/12/309

RESOLUTION [WRC-03] (WRC-2000)

Agenda for the 2003 World Radiocommunication Conference

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that, in accordance with Nos. **118** and **126** of the Convention (Geneva, 1992), the general scope of the agenda for a world radiocommunication conference should be established four years in advance and a final agenda shall be established two years before the conference;

b) Article 13 of the Constitution (Geneva, 1992) regarding the competence and scheduling of world radiocommunication conferences and Article 7 of the Convention (Geneva, 1992) regarding their agendas;

c) the relevant Resolutions and Recommendations of previous world administrative radio conferences (WARCs) and world radiocommunication conferences (WRCs),

recognizing

a) that this Conference has identified a number of urgent issues requiring further examination by WRC-03;

b) that in preparing this agenda, many proposals from administrations could not be included and have had to be deferred to future conference agendas,

resolves

to recommend to Council that a world radiocommunication conference be held in early 2003 for a period of three or four weeks, with the following agenda:

1 to take appropriate action in respect of those urgent issues that were specifically requested by the 2000 World Radiocommunication Conference (WRC-2000);

2 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, and taking account of the results of WRC-2000, to consider and take appropriate action in respect of the following topics:

2.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, taking into account Resolution **26 (Rev.WRC-97)**;

2.2 to consider the upgrade of allocations to the radiolocation service in the bands around 3 GHz and around 5.5 GHz;

2.3 to consider spectrum requirements for wideband aeronautical telemetry in the band between 3 GHz and 30 GHz;

2.4 to consider moving the existing additional allocation of the 7 145-7 235 MHz band on a primary basis pursuant to No. **S5.460** to within the frame of the Table of Frequency Allocations;

2.5 to consider inclusion in the Radio Regulations of power flux-density limits, in accordance with ITU-R Recommendation S.[Doc. 4/54], to protect the feeder uplinks of non-geostationary mobile-satellite service systems operating in the fixed-satellite service at 5 GHz pursuant to No. **S5.447A**;

2.6 examination of the adequacy of the frequency allocations for HF broadcasting from about 4 MHz to 10 MHz, taking into account the seasonal planning procedures adopted by WRC-97, and to consider bringing forward the date of availability of the HF bands allocated by WARC-92 to the broadcasting service in response to Resolution **29 (WRC-97)** and Resolution **537 (WRC-97)**;

2.7 to consider realignment of the allocations to the amateur, amateur-satellite, and broadcasting services around 7 MHz on a worldwide basis, taking into account Recommendation **718 (WARC-92)**;

2.8 possible allocations to passive services in the frequency bands above 275 GHz;

2.9 to consider an extension to the upper end of the current allocations to the EESS (active) and space research (active) from 5 460 MHz up to 5 570 MHz for the purpose of providing additional spectrum for spaceborne radio-altimetry and synthetic aperture radar imaging;

2.10 to consider the regulatory and technical provisions for satellite networks using highly elliptical orbits;

2.11 review allocations to the space research service (deep space) (space-to-Earth) and the inter-satellite service in the frequency range 32-32.3 GHz with a view to improving the sharing conditions between these services;

2.12 to consider possible extension of the allocation to the mobile-satellite service (Earth-to-space) on a secondary basis in the band 14-14.5 GHz to permit the aeronautical mobile-satellite service as stipulated in Resolution **216 (Rev.WRC-2000)**;

2.13 to examine the spectrum requirements for telemetry, tracking, and telecommand of FSS networks operating with service links in the frequency bands above 17 GHz;

3 to examine the revised ITU-R Recommendations incorporated by reference in the Radio Regulations which have been communicated by the 2003 Radiocommunication Assembly, in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with the principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;

4 to take actions consequential to resolutions of the Plenipotentiary Conferences, including review of procedures for satellite networks under Resolution **86** (Minneapolis, 1998);

5 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;

6 in accordance with Resolution **95 (WRC-97)**, to review the Resolutions and Recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

7 to review, and take appropriate action on, the Report from the Radiocommunication Assembly submitted in accordance with Nos. **135** and **136** of the Convention (Geneva, 1992);

8 to identify those items requiring urgent action by the radiocommunication study groups;

9 in accordance with Article 7 of the Convention (Geneva, 1992):

9.1 to consider and approve the Report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-2000;

9.2 to recommend to Council items for inclusion in the agenda for the 2005/6 World Radiocommunication Conference,

invites Council

to finalize the agenda and arrange for the convening of WRC-03 and to initiate as soon as possible the necessary consultation with Member States,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a Report to WRC-03,

instructs the Secretary-General

to communicate this Resolution to concerned international and regional organizations.

Reasons: Draft resolution for the next WRC.

2 Proposal for the preliminary agenda for the 2005/6 World Radiocommunication Conference

Background information

The United States proposal for the preliminary agenda for WRC-2005/6 is contained in Resolution [WRC-05/06].

ADD USA/12/310

DRAFT RESOLUTION [WRC-05/06] (WRC-2000)

Preliminary agenda for the 2005/6 World Radiocommunication Conference

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that, in accordance with Nos. **118** and **126** of the Convention of the International Telecommunication Union (Geneva, 1992), the general scope of the agenda for the 2005/6 World Radiocommunication Conference (WRC-05/06) should be established six years in advance;

b) Article 13 of the Constitution of the International Telecommunication Union (Geneva, 1992) regarding the competence and scheduling of world radiocommunication conferences and Article 7 of the Convention (Geneva, 1992) regarding their agendas;

c) the relevant Resolutions and Recommendations of previous world administrative radio conferences (WARCs) and world radiocommunication conferences (WRCs),

resolves to give the view

that the following items should be included in the preliminary agenda of WRC-06, to be held in 2005/6:

1 to take appropriate action in respect of those urgent issues that were specifically requested by the 2003 World Radiocommunication Conference (WRC-03);

2 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, and taking account of the results of WRC-2000, to consider and take appropriate action in respect of the following topics:

2.1 to consider Appendix **S13** and Resolution **331 (Rev.WRC-97)** with a view to their deletion and, if appropriate, consider related changes to Chapter SVII and other provisions of the Radio Regulations as necessary, taking into account the continued transition to the Global Maritime Distress and Safety System (GMDSS).

2.2 to consider the results of studies, and take necessary actions relating to shore-to-ship distress communication priorities (Resolution **348 (WRC-97)**);

2.2.1 to consider primary allocations to space research (passive) in existing primary radio astronomy bands below 10 GHz, excluding 322-328.6 MHz;

2.2.2 to review studies and related allocations if appropriate to the non-GSO MSS < 1 GHz in the 470-862 MHz band (Resolution **728 (WRC-97)**);

2.2.3 to review studies and related allocations if appropriate to the non-GSO MSS < 1 GHz in the 405-406 MHz band (Resolution **219 (WRC-97)**);

3 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;

4 in accordance with Resolution **95 (WRC-97)**, to review the Resolutions and Recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

5 to review, and take appropriate action on, the Report from the Radiocommunication Assembly submitted in accordance with Nos. **135** and **136** of the Convention (Geneva, 1992);

6 to identify those items requiring urgent action by the radiocommunication study groups;

7 in accordance with Article 7 of the Convention (Geneva, 1992):

7.1 to consider and approve the Report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-03;

7.2 to recommend to Council items for inclusion in the agenda for the 2009 World Radiocommunication Conference,

invites Council

to consider the views given in this Resolution,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a report to WRC-05/06,

instructs the Secretary-General

to communicate this Resolution to concerned international and regional organizations.

Reasons: United States proposed agenda items for WRC-05/06.

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROTECTION OF THE FIXED SERVICE FROM GSO FSS OPERATIONS IN THE 11.7 TO 12.2 GHz BAND (REGION 2)

Background information

The 11.7-12.2 GHz band is allocated to the fixed-satellite service (FSS) on a primary basis in Region 2, and the 11.7-12.1 GHz band is allocated to the fixed service (FS) on a primary basis in certain countries within Region 2 (See No. S5.486). The use of the 11.7-12.2 GHz band by FSS in Region 2 is subject to No. S5.488.

Recent modifications to No. S5.488 (previously RR No. 839) removed the explicit reference to No. S9.21 (previously Article 14). Consequently, at its 13th meeting in July 1998, the ITU Radio Regulations Board revised its Rule of Procedure for No. S5.488, stating that there is "no longer a need for the specific procedures of No. S9.21, in addition to the normally applicable coordination/agreement procedures of Article S9". The Board and certain administrations expressed the view that the omission of specific reference to No. S9.21 in No. S5.488 removed the regulatory mechanism available for protection of terrestrial services from GSO FSS downlinks. Notwithstanding, the requirement that FSS systems in the 11.7-12.2 GHz band (Region 2) obtain prior agreement with those "administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected" remains.

Section 7.6.3 of the CPM Report identifies three possible approaches for protection of terrestrial services from GSO FSS operations in the 11.7-12.2 GHz band (Region 2): 1) hard power flux-density (pfd) limits for GSO FSS networks in Region 2; 2) use of power flux-density levels as threshold values which, if exceeded, would require the agreement of affected administrations; 3) explicit reference to No. S9.21 in No. S5.488 consistent with the regulatory regime that was applied to the 11.7-12.2 GHz band in Region 2 for many years.

Although GSO FSS and fixed-service systems have successfully co-existed in the 11.7-12.2 GHz band (Region 2) for many years under Article 14/S9.21 consistent with approach 3), concerns have been expressed that application of the former S9.21 approach implements only a limited time period for comments in the regulatory process. This proposal is responsive to these concerns.

In support of approach 2) above, pfd thresholds are proposed because they provide the required flexibility for administrations implementing GSO FSS systems, while still affording protection to fixed service systems. Under certain circumstances it is necessary for GSO FSS operators to operate at an increased satellite downlink power in order to serve a particular geographic location (e.g. extreme latitudes served at lower elevation angles) or to provide certain types of carriers (e.g. analogue television, 16-QAM). Such power increases, however, will be minimized because satellite operators have a financial incentive to use only the minimum power required to close a link. Pfd thresholds allow for these types of GSO FSS operations, as necessary, provided that agreement is reached with any affected terrestrial administration. Pfd thresholds also allow for the advancement of satellite technology including the use of smaller antennas and higher/more efficient modulation schemes, particularly into under-served areas.

This document proposes to include in Appendix S5 of the Radio Regulations pfd levels to be used as thresholds for coordination of GSO FSS systems with fixed-service systems. These coordination thresholds would be applicable to GSO FSS systems in the 11.7-12.2 GHz band in Region 2. Under this approach, the requirement for coordination of GSO FSS networks operating in the 11.7-12.2 GHz band (Region 2) with terrestrial systems would be contained in a new provision of Article S9, ADD S9.20. An administration would send its coordination request to the ITU Radiocommunication Bureau (BR) pursuant to MOD S9.30. Upon receipt of the information, BR would identify those administrations with which coordination may need to be effected, based on exceedance of the pfd threshold levels contained in Appendix S5, and publish the names of the administrations in its Weekly Circular.

Because fixed-service systems in this band generally employ digital technologies, it is proposed to specify the pfd in a 1 MHz rather than a 4 kHz reference bandwidth. A 1 MHz reference bandwidth was also found appropriate for pfd limits applicable to non-GSO FSS systems in this frequency band. Therefore, the proposed level of protection to the fixed service from GSO FSS (space-to-Earth, Region 2) is as follows:

–124	dB(W/m^2) in 1 MHz	$\theta \leq 5°$
–124 + 0.5 (θ - 5)	dB(W/m^2) in 1 MHz	$5° \leq \theta \leq 25$
–114	dB(W/m^2) in 1 MHz	$25° \leq \theta \leq 90°$

The above protection levels are equivalent to the following levels in a 4 kHz reference bandwidth:

–148	dB(W/m^2) in 4 kHz	$\theta \leq 5°$
–148 + 0.5 (θ - 5)	dB(W/m^2) in 4 kHz	$5° \leq \theta \leq 25°$
–138	dB(W/m^2) in 4 kHz	$25° \leq \theta \leq 90°$

The proposed coordination threshold pfd levels are 2 dB more relaxed (i.e. higher) than the values contained in ITU-R Recommendation SF.674-1, *Power Flux-Density Values to Facilitate the Application of Article 14 of the Radio Regulations for FSS in Relation to the Fixed-Satellite Service in the 11.7-12.2 GHz Band in Region 2*. This 2 dB relaxation is proposed in order for the Radio Regulations to be more representative of the actual operating conditions in this frequency band.

If hard limits as opposed to coordination thresholds were to be included in Article S21 of the Radio Regulations, the limits would need to be considerably more relaxed (i.e. higher) than the levels above in order to accurately reflect the existing and planned use of the band. It should be noted that ITU-R has not studied the pfd levels that would be appropriate as hard limits in the 11.7-12.2 GHz band segment. Because of the varying satellite and terrestrial system characteristics throughout the 10.7-12.75 GHz band segments, it is not appropriate to extrapolate pfd limits to other frequency band segments.

ARTICLE S5

Frequency allocations

MOD USA/12/303

S5.488 The use of the bands 11.7-12.2 GHz by the fixed-satellite service in Region 2 and 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7-12.2 GHz by geostationary satellite networks in the fixed-satellite service in Region 2 is subject to ~~previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9** and **S11**)~~coordination under No. **S9.20**. For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

ARTICLE S9

Section II – Procedure for effecting coordination[8, 9]

Sub-Section IIA – Requirement and request for coordination

ADD USA/12/304

S9.20 i*bis)* for a transmitting space station of the fixed-satellite service using the geostationary-satellite orbit in respect of stations of terrestrial services where the threshold value is exceeded on the territory of another administration;

MOD USA/12/305

S9.30 Requests for coordination made under Nos. **S9.7** to **S9.14**, **S9.20** and **S9.21** shall be sent by the requesting administration to the Bureau, together with the appropriate information listed in Appendix **S4** to these Regulations.

MOD USA/12/306

S9.51 Following its action under No. **S9.50**, the administration with which coordination was sought under Nos. **S9.7** to **S9.9** and **S9.20** shall, within four months of the date of publication of the Weekly Circular under No. **S9.38**, either inform the requesting administration and the Bureau of its agreement or act under No. **S9.52**.

MOD USA/12/307

S9.60 If, within the same four-month period specified in Nos. **S9.51** or **S9.51A**, an administration with which coordination is sought under Nos. **S9.7** to **S9.9** and **S9.15** to ~~**S9.19**~~**S9.20** fails to reply or to give a decision under Nos. **S9.51** or **S9.51A** or, following its disagreement under No. **S9.52**, fails to provide information concerning its own assignments on which its disagreement is based, the requesting administration may seek the assistance of the Bureau.

No. **ADD S9.20** GSO/terrestrial	For a transmitting space station of the fixed-satellite service using the geostationary-satellite orbit in respect of stations of terrestrial services where the threshold value is exceeded	11.7-12.2 GHz (Region 2)	The power flux-density at the surface of the Earth, for angles or arrival (θ) above the horizontal plane, produced by emissions from a space station, including emissions from a reflecting satellite, exceed limits as follows: -124 dB(W/m^2) in 1 MHz for $\theta \leq 5°$ $-124 + 0.5\ (\theta - 5)$ dB (W/m^2) in 1 MHz for $5° \leq \theta \leq 25°$ -114 dB(W/m^2) in 1 MHz for $25° \leq \theta \leq 90°$	Check for exceedance of the threshold/condition	The limits relate to the power flux-density which would be obtained under assumed free-space propagation conditions

Formatted

Reasons: Specific modifications to Articles S5, S9 and Appendix S5 of the Radio Regulations are proposed to include pfd coordination thresholds in the Radio Regulations, as identified in section 7.6.3 of the CPM Report, Approach 2. Pfd thresholds are proposed because they provide the flexibility required for GSO FSS systems to provide analogue TV and higher/more efficient modulation schemes, while still affording protection to fixed-service systems. In response to concerns expressed by terrestrial administrations, the proposed regulatory regime requires administrations to send its coordination requests to the ITU BR. Upon receipt of the information, the BR would identify those administrations with which coordination may need to be effected, based on an exceedance of the pfd threshold levels contained in Appendix S5, and publish the names of the administrations in its Weekly Circular.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 15 to
Document 12-E
17 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 4 - in accordance with Resolution 95 (WRC-97), to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation

Proposal to amend Resolution 127

Background information

The proposal herein amends Resolution 127 to take account of the current status of ITU-R studies on the compatibility of non-GSO MSS feeder links in bands around 1.4 GHz with services in the same and nearby bands; and to invite WRC-03 to consider allocations to non-GSO MSS feeder links in bands around 1.4 GHz on the basis of completed studies.

References: ITU-R Document 8D/251, ITU-R WP 8D/317, Attachment 4

Resolution 127, adopted at WRC-97, resolved that studies should be carried out as a matter of urgency on the operational and technical measures required:

i) to facilitate sharing between feeder links for non-GSO MSS systems and existing and currently planned services in portions of the band 1 390-1 400 MHz (Earth-to-space) and 1 427-1 432 MHz (space-to-Earth); and

ii) to protect passive services in the band 1 400-1 427 MHz from unwanted emissions from feeder links for non-GSO MSS systems;

and invited a future competent conference to consider, on the basis of completion of the above-mentioned studies, additional allocations for feeder links on a worldwide basis for non-GSO MSS systems with service links below 1 GHz.

Item 3.5 of Resolution 722, “Preliminary agenda for the 2001 World Radiocommunication Conference”, included an item on consideration of the results of studies related to additional allocations on a worldwide basis for feeder links in bands around 1.4 GHz to the non-geostationary mobile-satellite services with service links operating below 1 GHz, taking into account studies conducted in response to Resolution 127.

This proposal would amend Resolution 127 to have it call for allocations based on completion of studies on the agenda of WRC-03.

The rationale for including consideration of allocations to MSS feeder links near 1.4 GHz in the agenda of WRC-03 is that theoretical studies referred to in Resolution 127 have been completed and accepted, and that the remaining hardware demonstrations are planned for completion prior to the convening of WRC-03.

Therefore, WRC-03 will likely have before it the technical and sharing measures, and sharing and compatibility studies that would enable it to consider additional allocations around 1.4 GHz to non-GSO MSS for feeder links.

The studies performed to date indicate that out-of-band emissions from MSS feeder links at 1 390-1 393 MHz (up), and 1 429-1 432 MHz (down) into the band 1 400-1 427 MHz, which is allocated on a primary basis exclusively to sensitive, passive science services, can be reduced through the use of highly efficient modulation methods such as GMSK, and through careful design, which will keep intermodulation products out of that neighbouring band.

Those studies now have a certain measure of acceptance from the science services themselves (Document ITU-R 8D/251). The current or remaining concerns of these services - radio astronomy, Earth exploration-satellite (passive), and space research (passive) - are whether the results indicated by theory and preliminary measurement and testing can be achieved throughout the life of operational spacecraft. It is these latter tests, among others, that are planned to be available before WRC-03 convenes.

If the additional tests and measurements are persuasive, but the item was not previously put on the agenda of WRC-03 by WRC-2000, then the conference would not be competent to consider those allocations.

If the additional tests and measurements that would be conducted between now and the convening of WRC-03 are not persuasive, and the item is on its agenda, then WRC-03 would not, in its good judgement, make any such allocations, even though it was competent to do so. In other words, putting the item on the preliminary agenda of WRC-03 is both foresighted and “fail-safe”.

Supporting information

A detailed discussion of the compatibility of feeder links around 1.4 GHz with the science services in a nearby band can be found in the Chairman’s Report of the April 1999 WP 8D meeting, ITU-R Document WP 8D/317, Attachment 4.

MOD USA/12/287

RESOLUTION 127 (WRC-2000)

Studies relating to consideration of allocations in bands around 1.4 GHz for feeder links of the non-geostationary-satellite systems in the mobile-satellite service with service links operating below 1 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

MOD USA/12/288

a) that the agenda of WRC-97 included consideration of the adoption of additional allocations for the non-geostationary (non-GSO) mobile-satellite service (MSS);

MOD USA/12/289

b) that the Report of the 1999 Conference Preparatory Meeting (CPM-99) stated that the Radiocommunication Bureau has identified 25 non-GSO MSS networks as of 26 November 1999 at frequencies below 1 GHz, at some stage of coordination under Resolution **46 (Rev.WRC-97)**, and that many of the proposed networks cannot be implemented in the existing allocations because there is not enough spectrum;

c) that CPM-97 stated that due to the extreme sensitivity of radio astronomy observations interference from unwanted (spurious and out-of-band) emissions can be a problem, but also noted that interference to radio astronomy can be avoided using various techniques including low-power transmitter levels, choice of modulation, bit shaping, output filtering and band limiting filters, the use of which can minimize the band separation necessary to meet the recommended interference threshold levels for out-of-band emissions;

SUP USA/12/290

d)

MOD USA/12/291

d) that factors taken into account by post-CPM-97 activities in order to protect the passive services around 1.4 GHz from out-of-band emissions include: the use of narrow-band non-GSO MSS feeder-link transmissions; the use of spectrum-efficient modulation methods, such as Gaussian filtered minimum shift keying, having inherently rapid roll-off of out-of-band emissions; the use, where necessary, of band-pass filters in satellite transmitters and MSS feeder-link transmitting earth stations; and guardbands where necessary;

MOD USA/12/292

e) that factors taken into account by post-CPM-97 activities concerning sharing with the radiolocation service include the use of conventional techniques that may be applied in MSS satellite receivers, such as intermediate frequency limiters and time diversity, which have long been employed to protect radiolocation receivers, and techniques such as transmitted waveforms employing time diversity, which have been employed to protect receivers in other services from high-power pulsed radar transmitters;

MOD USA/12/293

f) that, since CPM-97, ITU studies have been carried out containing theoretical analyses with a view to determining if the operation of non-GSO MSS feeder links in bands around 1.4 GHz would be compatible with the Earth exploration-satellite (passive), radio astronomy and space research (passive) services;

ADD USA/12/294

g) that the theoretical analyses have indicated that sufficient reduction of out-of-band and spurious emissions could be achieved to protect the sensitive science services in nearby bands;

ADD USA/12/295

h) that additional tests and measurements of feeder-link transmissions from systems having the characteristics, performance, and reliability of equipment that would be used in operational systems are necessary;

ADD USA/12/296

i) that such additional tests and measurements will be completed prior to WRC-03,

recognizing

that the bands near 1.4 GHz are extensively used by many other services operating in accordance with the Radio Regulations, including fixed and mobile services,

noting

a) that Resolution **214 (Rev.WRC-97)** states under *resolves* 1. that further studies are urgently required on operational and technical means to facilitate sharing between non-GSO MSS and other radiocommunication services having allocations and operating below 1 GHz;

SUP USA/12/297

b)

c)

MOD USA/12/298

b) that, since WRC-95, ITU-R studies have been carried out on sharing between space and terrestrial services and feeder links near 1.4 GHz for non-GSO MSS systems with service links below 1 GHz,

resolves

MOD USA/12/299

1 to invite ITU-R, as a matter of urgency, to continue studies, and to carry out additional tests and demonstrations to validate the studies on operational and technical measures required to facilitate sharing in portions of the band 1 390-1 393 MHz between existing and currently planned services and feeder links (Earth-to-space) for non-GSO MSS systems with service links operating below 1 GHz;

MOD USA/12/300

2 to invite ITU-R, as a matter of urgency, to carry out additional tests and demonstrations to validate the studies on operational and technical means to facilitate sharing, in portions of the band 1 429-1 432 MHz, between existing and currently planned services and feeder links (space-to-Earth) for non-GSO MSS systems with service links operating below 1 GHz;

MOD USA/12/301

3 to invite ITU-R, as a matter of urgency, to carry out additional studies, including the measurement of emissions from equipment that would be employed in operational systems to protect passive services in the band 1 400-1 427 MHz from unwanted emissions from feeder links near 1.4 GHz for non-GSO MSS systems with service links operating below 1 GHz;

MOD USA/12/302

4 to invite WRC-03 to consider, on the basis of completion of studies referred to in *resolves* 1, 2 and 3, additional allocations for feeder links on a worldwide basis for non-GSO MSS systems with service links below 1 GHz,

urges administrations

to participate actively in such studies, with the involvement of interested parties.

Reasons: To take account of the current status of ITU-R studies on the compatibility of non-GSO MSS feeder links in bands around 1.4 GHz with services in the same and nearby bands, and to invite WRC-03 to include in its agenda consideration of allocations to non-GSO MSS feeder links in bands around 1.4 GHz.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 14 to
Document 12-E
14 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.11 - to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions 214 (Rev.WRC-97) and 219 (WRC-97)

Proposal to amend Resolution 219

Background information

The proposal herein amends Resolution 219 to take into account the most recent studies supporting the need for additional spectrum for non-GSO MSS, and the possibility of increasing the efficiency of spectrum utilization in the band 401-406 MHz by existing systems. These efficiencies might make it possible for a portion of the band segment 405-406 MHz to be allocated to non-GSO MSS.

Resolution 219, adopted at WRC-97, noted the significant shortfall of spectrum for non-GSO MSS below 1 GHz and that there is an urgent need to make additional spectrum available on a worldwide basis for such systems.

It also noted that the development of more spectrum-efficient meteorological aids systems is continuing in order to minimize the bandwidth required by these systems.

Initial studies conducted under Resolution 219 focused on improving the frequency stability of the narrow-band radiosondes, but it was felt that the cost of this improvement was more than many administrations could support. Additionally, the upgrading of the EES and the meteorological satellite to primary status in the 401-403 MHz portion of the band has incurred a fear that the MetAids (radiosondes) may eventually be forced out of these two MHz of spectrum. As a result, the WMO has stated that it needs to retain the use of 405-406 MHz based on the earlier narrow-band radiosonde improvement studies carried out under Resolution 219.

The proposed modified Resolution carries forward the invitation to ITU-R to study such more spectrum-efficient technologies and operational techniques on an urgent basis.

We propose that WRC-06 should consider the results of these studies in accordance with Resolution 219, and an allocation to the NVNG MSS in the 405-406 MHz band if warranted.

Studies are under way to examine spectrum efficient utilization of this band which might alleviate the WMO concerns about the effects of the EES and MetSat upgrading to primary status in the 401-403 MHz portion of the band. A preliminary study of one such spectrum-efficient technology, based on radiosondes using direct-sequence spread-spectrum (DSSS), was submitted to WP 7C (Document ITU-R WP 7C/201) in January 2000 for its consideration. While several problems and limitations of the DSSS approach have been noted in the United States and elsewhere, the spread-spectrum approach may have potential, and further study is continuing.

MOD USA/12/275

RESOLUTION 219 (Rev.WRC-~~97~~2000)

Studies relating to consideration of the allocation to the non-geostationary mobile-satellite service in the meteorological aids band 405-406 MHz and the impact on primary services allocated in the adjacent bands

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that there is a significant shortfall of spectrum for the non-geostationary (non-GSO) mobile-satellite service (MSS) below 1 GHz, and there is an urgent need to make additional spectrum available on a worldwide basis for such non-GSO MSS systems;

MOD USA/12/276

b) that the Report of the ~~1997~~1999 Conference Preparatory Meeting (CPM-9~~7~~9) to ~~this Conference~~WRC-2000 state~~s~~d that the Radiocommunication Bureau has identified 2~~3~~5 non-GSO MSS networks, at frequencies below 1 GHz, at some state of coordination under Resolution **46 (Rev.WRC-97)**/No. **S9.11A** of the Radio Regulations, that it is likely that a number of these systems may not be implemented for reasons not connected with spectrum availability and that several administrations have indicated in their information submitted to the Bureau that they plan on implementing these non-GSO MSS systems by the year 2002 or earlier. However, CPM also recognized that many of the proposed networks cannot be implemented in the existing allocation;

SUP USA/12/277

c)

ADD USA/12/278

c) that the CPM Report for WRC-2000 identified a need for spectrum beyond the current allocations, identifying a spectrum requirement for service links of about 17 MHz on a shared basis, and an additional 4 MHz of shared spectrum for feeder links; and that recent reports carried out in 1997-1998 support these original 1996 study estimates;

d) that meteorological aids systems are essential to produce the upper air measurements required by the World Meteorological Organization (WMO), as summarized in Recommendation ITU-R SA.1165, and that systems using the band 400.15-406 MHz constitute the majority of the mobile and fixed observation stations worldwide;

e) that meteorological aids systems are also essential to produce the upper air measurements required for civilian and other applications;

f) that the amount of spectrum required by meteorological users, including WMO (station spacing requirement of 250 km), civilian users and other related users, in most geographical areas is about 5 MHz in the band 401-406 MHz using the currently employed technology;

MOD USA/12/279

g) that since ~~this Conference~~WRC-97 upgraded the allocation to the Earth exploration-satellite service and the meteorological-satellite service to primary in the band 401-403 MHz, this is likely to impose constraints on the meteorological aids service in this band in certain geographical areas;

ADD USA/12/280

h) that the CPM Report for WRC-2000 stated that in the long term, improved technology and operational techniques may result in more efficient use of the band 401-406 MHz by the existing services, which may enable future review of requirements for this band;

MOD USA/12/281

~~h~~i) that the development of more spectrum-efficient meteorological aids systems is continuing in order to minimize the bandwidth required by these systems, as outlined in Recommendation ITU-R SA.1165, and that recent development of these related technologies has been rapid;

~~i~~j) that sharing studies to date have shown that co-channel sharing between currently proposed non-GSO MSS systems and meteorological aids in the band 401-406 MHz is not generally feasible, that any sharing would require band segmentation and that the band 405-406 MHz has been named by some administrations as a possible candidate band for such a new allocation;

~~j~~k) that any transition of meteorological aids from the band 405-406 MHz should not increase the operational costs of meteorological aids networks beyond the available financial resources, and should not constrain the future development of the meteorological aids service, while using more spectrum-efficient systems;

~~k~~l) that the COSPAS-SARSAT system operates within an exclusive allocation in the band 406-406.1 MHz, that the radio astronomy service has a primary allocation in the band 406.1-410 MHz and that these services need to be protected from MSS transmissions including unwanted emissions,

noting

a) that the possible use of the band 405-406 MHz by the MSS should be limited to systems using narrow-band modulation techniques until further ITU-R studies conclude that other modulation techniques can protect COSPAS-SARSAT (406-406.1 MHz) and the radio astronomy service (406.1-410 MHz);

b) that Resolution **214 (Rev.WRC-97)** also addresses sharing studies relating to consideration of the allocation of bands below 1 GHz to the non-GSO MSS,

resolves to invite ITU-R

ADD USA/12/282

1 as a matter of urgency, to study improved technology and operational techniques which may result in more efficient use of the band 401-406 MHz by the existing services;

MOD USA/12/283

~~1~~2 as a matter of urgency, upon completion of the studies in *resolves* 1, with the participation of WMO, to assess further the current and future requirements of the meteorological aids service in the band 401-406 MHz, taking into account the requirements of the earth exploration-satellite service and the meteorological-satellite service in the band 401-403 MHz;

~~2~~3 as a matter of urgency, upon completion of the studies in *resolves* 1, with the participation of WMO, to consider the possible transition of the meteorological aids service out of a portion of the band 405-406 MHz, which would minimize the impact on the meteorological aids service, while taking into account requirements for the implementation of non-GSO MSS;

MOD USA/12/284

~~3~~4 to consider, based on the outcome of § 1 and 2 above, a possible transition plan, including a transition date at which time meteorological aids could migrate their operations out of a portion of the band 405-406 MHz and MSS operations could commence;

~~4~~5 as a matter of urgency, to study, with the participation of the Inter-Union Commission on Frequency Allocations for Radio Astronomy and Space Science (IUCAF) and other relevant entities, the impact of unwanted emissions on the COSPAS-SARSAT system in the band 406-406.1 MHz and the radio astronomy service in the band 406.1-410 MHz, and identify appropriate protection measures for these services,

resolves

MOD USA/12/285

that ~~WRC-99~~the World Radiocommunication Conference (WRC-06) be invited to consider, based on the outcome of *resolves to invite ITU-R* above, the possibility of allocating a portion of the band 405-406 MHz to the ~~MSS~~, including any appropriate transition plan,

urges administrations

1 to assess their current and future requirements for meteorological aids systems in the band 401-406 MHz taking into account the requirements of the Earth exploration-satellite service and the meteorological-satellite service in the 401-403 MHz band;

MOD USA/12/286

2 to, either individually or on a subregional or regional basis, report to WMO and ITU-R on whether the whole of the band 401-406 MHz will be needed for meteorological aids, and the possibility of transition out of a portion of the band 405-406 MHz;

3 to submit to ITU-R the most up-to-date information on their plans for possible implementation of non-GSO MSS systems and the associated spectrum requirements,

instructs the Secretary-General

to bring this Resolution to the attention of WMO.

Reasons: To take account of the continuing need for additional spectrum below 1 GHz for non-GSO MSS service links, and to impart a greater sense of urgency to the development of more spectrum-efficient techniques by meteorological aids systems in the band 401-406 MHz.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 13 to Document 12-E
26 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Proposal for agenda item 1.11 - to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking into account the results of ITU-R studies conducted in response to Resolutions 214 (Rev.WRC-97) and 219 (WRC-97)

MODIFICATION OF RESOLUTION 214 (Rev.WRC-97)

Sharing studies relating to consideration of the allocation of bands below 1 GHz to the non-geostationary mobile-satellite service

Background information

The CPM Report to WRC-2000 indicates a requirement of 7 to 17 MHz of additional spectrum required for service links in the non-geostationary mobile-satellite service (non-GSO MSS) below 1 GHz. Additionally, 4 MHz of shared spectrum is identified as the required spectrum for MSS feeder links. These requirements will not likely be met by additional allocations to the non-GSO MSS at WRC-2000. Thus, there remains an urgent need for usable spectrum to be made available on a worldwide basis for non-GSO MSS systems operating below 1 GHz.

In response to Resolution 214 (Rev.WRC-97), ITU-R studies have shown that for specific cases, co-frequency sharing between the non-GSO MSS and the existing services below 1 GHz may be achieved. However, other cases have not been taken into account. Consequently, the operational and technical means to facilitate sharing have not been studied for some systems operating in some parts of the world.

The continued study and development of Recommendations by ITU-R on the performance requirements, sharing criteria and the technical and operational issues relating to sharing between the existing services and non-GSO MSS below 1 GHz can provide the technical basis for consideration at WRC-03 of additional allocations on a worldwide basis for the non-GSO MSS below 1 GHz. Therefore, the United States proposes the continuance of Resolution 214 as modified by this proposal.

Consideration of the technical and regulatory constraints on non-GSO MSS allocations in the bands below 1 GHz was addressed by WRC-2000. Therefore, that aspect is proposed for deletion from Resolution 214.

It is proposed to modify Resolution 214 (Rev.WRC-97):

1) to invite continued ITU-R study of the technical and operational measures to facilitate sharing between the non-GSO MSS and existing services below 1 GHz;

2) to invite WRC-03 consideration of additional allocations to the non-GSO MSS below 1 GHz;

3) to delete from Resolution 214 the consideration of technical and regulatory constraints on the non-GSO MSS allocations in the bands below 1 GHz, which was addressed by WRC-2000.

MOD USA/12/257

RESOLUTION 214 (Rev.WRC-97)

Sharing studies relating to consideration of the allocation of bands below 1 GHz to the non-geostationary mobile-satellite service

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that the agenda of this Conference included consideration of additional allocations on a worldwide basis for the non-geostationary mobile-satellite service (non-GSO MSS) below 1 GHz;

b) that the 199~~7~~9 Conference Preparatory Meeting, in its Report, indicated that for the non-GSO MSS below 1 GHz there is not enough spectrum currently allocated to allow development of all the systems currently in coordination, and that, in order to meet projected MSS requirements below 1 GHz, a range of an additional 7 to 10 MHz will be required in the near future although, as well, it recognized that a number of these systems may not be implemented for reasons not connected with spectrum availability;

Reasons: Editorial.

c) that there is an urgent need to make usable spectrum available on a worldwide basis for non-GSO MSS systems operating below 1 GHz;

d) that some non-GSO MSS systems are already operated by some administrations in existing MSS allocations and are at an advanced stage of consideration for operation in many other administrations, and that studies have been conducted within ITU-R on sharing between non-GSO MSS and certain terrestrial services which demonstrate the feasibility of sharing in the cases studied;

e) that issues concerning the technical and operational means to facilitate sharing between the terrestrial services and non-GSO MSS in the bands below 1 GHz remain to be studied;

f) that the requirements for the introduction of these new technologies have to be balanced with the needs of other services having allocations below 1 GHz;

g) that the bands below 1 GHz are extensively used by administrations for many services, although the extent to which they are used by each administration varies throughout the world,

noting

MOD USA/12/258

a) that additional studies may identify ~~other~~suitable bands below 1 GHz ~~which could also~~and appropriate sharing techniques to be considered ~~suitable~~ for ~~a~~ worldwide allocations to non-GSO MSS;

SUP USA/12/259

b)

MOD USA/12/260

~~e~~b) that constraints on the duration of any single transmission from an individual MSS mobile earth station and constraints on the period between consecutive transmissions from an individual MSS mobile earth station operating on the same frequency may facilitate sharing with terrestrial services;

MOD USA/12/261

~~d~~c) that interference mitigation techniques, such as the dynamic channel activity assignment system described in Recommendation ITU-R M.1039~~-1~~, may be used by non-GSO MSS systems below 1 GHz in the Earth-to-space direction to promote compatibility with terrestrial systems when operating in the same frequency band;

MOD USA/12/262

~~e~~d) that new technologies employed by some radiocommunication services, especially within the terrestrial mobile and broadcasting services, which require spectrum below 1 GHz, may have an impact on the sharing possibilities;

ADD USA/12/263

e) that substantial progress has been made by the completion of ITU-R studies to date of sharing between the non-GSO MSS below 1 GHz and existing specific services, however, studies on some important issues remain to be completed;

MOD USA/12/264

f) that non-GSO MSS systems operating below 1 GHz have undergone advance publication by the Radiocommunication Bureau and that administrations may seek to implement further such systems~~;~~,

SUP USA/12/265

g)

resolves

1 that further studies are urgently required on operational and technical means to facilitate sharing between the non-GSO MSS and other radiocommunication services having allocations and operating below 1 GHz;

MOD USA/12/266

2 that WRC-~~99~~03 be invited to consider, on the basis of the results of the studies conducted within ITU-R and the studies referred to in *resolves* 1 above, additional allocations on a worldwide basis for the non-GSO MSS below 1 GHz;

MOD USA/12/267

3 that relevant entities and organizations be invited to participate in these sharing studies~~;~~,

SUP USA/12/268

4

invites ITU-R

MOD USA/12/269

1 to study and develop Recommendations on, as a matter of urgency, the performance requirements, sharing criteria and technical and operational issues relating to sharing between ~~both~~ existing ~~and planned~~ services and non-GSO MSS below 1 GHz;

SUP USA/12/270

2

MOD USA/12/271

~~3~~2 as a matter of urgency, to carry out studies in preparation for WRC-~~99~~03 with respect to interference mitigation techniques, such as the dynamic channel activity assignment system described in Recommendation ITU-R M.1039~~-1~~, necessary to permit the continued development of all of the services to which the bands are allocated;

SUP USA/12/272

4

MOD USA/12/273

~~5~~3 to bring the results of these studies to the attention of WRC-~~99~~03 and the relevant preparatory meetings,

urges administrations

1 to participate actively in these studies, with the involvement of both terrestrial and satellite interests;

2 to submit to ITU-R reports on their technical studies and on their operational and frequency sharing experience with non-GSO MSS systems operating below 1 GHz,

encourages administrations

MOD USA/12/274

to consider the use of dynamic channel assignment techniques, such as those described in Recommendation ITU-R M.1039~~-1~~.

Reasons: There remains an urgent need for usable spectrum to be made available on a worldwide basis for non-GSO MSS systems operating below 1 GHz. Requirements have been identified for 7 to 17 MHz of additional spectrum for service links in the non-GSO MSS below 1 GHz and an additional 4 MHz for MSS feeder links.

The continued study and development of Recommendations by ITU-R on the performance requirements, sharing criteria and the technical and operational issues relating to sharing between the existing services and non-GSO MSS below 1 GHz can provide the technical basis for consideration at WRC-03 of additional allocations on a worldwide basis for the non-GSO MSS below 1 GHz. Therefore, the United States proposes the continuance of Resolution 214 as modified by this proposal.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 12 to Document 12-E
17 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 4 - in accordance with Resolution 95 (WRC-97), to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation

Proposal to amend Resolution 728 (WRC-97)

Background information

The proposal herein amends Resolution 728 to invite additional studies on feasibility of, and techniques to facilitate, sharing between non-GSO MSS (space-to-Earth) transmissions and digital television systems in the band 470-862 MHz; and to invite WRC-06 to consider the results of these studies with a view to including in the agenda of a future conference additional allocations on a worldwide basis in the band 470-862 MHz for the non-GSO MSS in accordance with Resolution 728.

Resolution 728, adopted at WRC-97, resolved in part:

1 to invite ITU-R to carry out studies to determine operational and technical means that may facilitate co-frequency sharing between narrow-band non-GSO MSS (space-to-Earth) transmissions and the services to which the band 470-862 MHz is allocated, including the bands where the broadcasting service is also allocated;

2 to invite a future competent conference to consider, on the basis of the results of the studies referred to in *resolves* 1, the possibility of making additional allocations on a worldwide basis for non-GSO MSS …

Existing Recommendations of ITU-R indicate that operation of narrow-band non-GSO MSS transmissions might be feasible at the edges of analogue television channels where the TV signal is least sensitive to interference. However, ITU-R Recommendations have not identified the protection ratios for digital television systems. To the extent that protection ratios for digital television are similar to those for analogue systems, the same conclusions on the feasibility of sharing would apply.

The proposed revision of Resolution 728 invites additional study of sharing, including consideration of digital television systems.

The existing Resolution does not identify a specific conference at which additional allocations to non-GSO MSS in the band 470-862 MHz could be considered. Therefore, it is foresighted and prudent to designate WRC-06 to review studies to date in order to establish the next conference at which allocations could be considered.

The proposed revision of Resolution 728 invites WRC-06, a conference that would convene six years after the adoption of the revised Resolution calling for additional studies, to review such studies related to additional allocations. In view of the current plans for the rapid design, development, testing, and installation of digital television systems, it is likely that the results of such studies would be available in time for consideration by WRC-06.

The feasibility of MSS sharing with broadcasting and other radiocommunication services in this band requires further study in ITU-R.

MOD USA/12/253

RESOLUTION 728 (Rev.WRC-~~97~~2000)

Studies relating to consideration of allocations in the broadcasting band 470-862 MHz to non-geostationary mobile-satellite services

The World Radiocommunication Conference (~~Geneva~~Istanbul, ~~1997~~2000),

considering

a) that the agenda of ~~WRC-97~~this Conference included consideration of the adoption of additional allocations for non-geostationary mobile-satellite services (non-GSO MSSs);

MOD USA/12/254

b) that the Report of the 199~~7~~9 Conference Preparatory Meeting (CPM-9~~7~~9) stated that the Radiocommunication Bureau has identified at least [~~23~~22] non-GSO MSS networks [as of 28 April 1999] at frequencies below 1 GHz, at some stage of coordination under Resolution **46**, and that many of the proposed networks cannot be implemented in the existing allocations because there is not enough spectrum;

c) that CPM-97 considered the protection requirements for analogue television in the band 470-862 MHz against a narrow-band MSS signal in the most sensitive and least sensitive portions of an analogue television channel and the protection requirements for a digital television channel, based on existing Recommendations ITU-R BT.655-4, ITU-R BT.417-4 and ITU-R IS.851-1;

d) that CPM-97 stated that the protection ratios for a narrow-band interfering signal in the least sensitive parts of an analogue television channel are to be verified by further studies;

e) that CPM-97 stated the region of lower protection requirements and commensurately higher permissible interfering power flux-density levels as being 100 kHz from the band edges of an analogue television channel, at least in some countries;

f) that CPM-97 stated that the interfering effects of a non-GSO MSS transmission will depend on its specific characteristics (e.g. duty-cycle, duration, periodicity, etc.), that interference contributions from sources other than MSS (even those from other broadcasting stations) have to be taken into account, that slightly lower values of field strength to be protected may need to be assumed in countries where television networks are relatively sparse, and that studies on sharing are necessary;

g) that the permissible aggregate interfering power flux-density resulting from these protection requirements, in some portions of an analogue television channel, may be useful in determining the feasibility of sharing with non-GSO MSS transmitter space-to-Earth links;

h) that these bands are also allocated in part to fixed and mobile terrestrial systems and radionavigation systems;

i) that, in many countries, the channels assigned for analogue television may also be used for digital television, and that during the period of parallel operation of analogue and digital television networks the usage of this band for television will increase,

noting

a) that on completion of studies, parts of the bands now allocated to the broadcasting service between 470 MHz and 862 MHz might be considered suitable for worldwide allocation to non-GSO MSS space-to-Earth transmissions;

b) that the bandwidth required in these television channels may be 1-2% of the total band 470-862 MHz to be shared with the above systems;

c) the need to protect the radio astronomy service in the band 608-614 MHz against interference from MSS transmissions, including unwanted emissions,

resolves

MOD USA/12/255

1 to invite ITU-R to carry out additional studies to determine operational and technical means that may facilitate co-frequency sharing between narrow-band non-GSO MSS (space-to-Earth) transmissions and the services to which the band 470-862 MHz is allocated, including the bands where the broadcasting service is also allocated, and including consideration of digital television systems;

MOD USA/12/256

2 to invite ~~a future competent conference~~WRC-06 to consider, on the basis of the results of the studies referred to in *resolves* 1, the possibility of making additional allocations on a worldwide basis for non-GSO MSS, taking into account, in particular, *considering h)* and *i)* above, with a view to considering allocations at a future conference,

urges administrations

to participate actively in such studies, with the involvement of interested parties.

Reasons: To extend the mandate of Resolution 728 to schedule a review of studies related to allocations at WRC-06, by which time studies can be completed based on the additional guidance of WRC-2000, and taking into account the interference and sharing criteria of digital TV broadcasting systems.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

Document 12-E
11 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

AGENDA ITEM 1.13

Proposed modifications to Resolution 130 (WRC-97)

Background information

In Resolution 130, WRC-97 established the sharing regime for non-GSO FSS and GSO FSS systems in certain frequencies between 10 and 30 GHz, specified provisional power limits for non-GSO FSS systems, and commenced a detailed study programme within ITU-R. After nearly three additional years of study in ITU-R, final power limits are expected to be adopted at WRC-2000. With the adoption of final power limits, many of the transitional provisions of Resolution 130 from WRC-97 can be suppressed, while certain non-transitional provisions are identified for reflection in the body of the Radio Regulations. The Annex containing provisional limits can also be suppressed.

There are elements of Resolution 130 that need to be retained. Indeed, CPM-99 recognized that there is a need to retain a suitably-modified Resolution 130, and provided in Annex 5 to Chapter 3 an example modification to Resolution 130 that forms the basis for these proposals. For example, studies on sharing among non-GSO FSS systems and studies on the appropriate frequency-sharing mechanism to employ in other bands where non-GSO FSS systems have been proposed.

The following proposals identify those elements of Resolution 130 (WRC-97) that are appropriate for suppression, retention, or updating, and present additional elements that have arisen during the 1997-2000 ITU-R study cycle requiring further study. While this proposal includes a request for further study on the aggregate $epfd_{down}$ limits and associated percentages of time for protection of the 3 m and 10 m GSO FSS earth stations, as referenced in the CITEL proposal on Resolution WWW (WRC-2000), the United States does not propose that the single entry validation, operational or additional operational limits be reconsidered.

MOD USA/12/202

RESOLUTION 130 (Rev.WRC-~~97~~2000)

Use of non-geostationary systems in the fixed-satellite service in certain frequency bands

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

Reasons: Editorial.

considering

a) that the International Telecommunication Union has, among its purposes, "to promote the extension of the benefit of the new telecommunication technologies to all the world's inhabitants" (No. 6 of the Constitution of the International Telecommunication Union (Geneva, 1992));

b) that it is desirable, in this respect, to promote systems capable of providing universal service;

c) that new telecommunication services need advanced and reliable networks permitting high-capacity communications;

d) the need to encourage the development and implementation of new technologies;

e) that systems based on the use of new technologies associated with both geostationary (GSO) and non-geostationary (non-GSO) satellite constellations are capable of providing the most isolated regions of the world with high-capacity and low-cost means of communication;

f) that there should be equitable access to the radio-frequency spectrum and orbital resources in a mutually acceptable manner that allows for new entrants in the provision of services;

g) that all Member States [‡] would benefit from the implementation of proposed systems in the allocated spectrum and from avoidance of monopolization or exclusive use of an allocation by a single system;

h) that the operation of such systems requires a suitable amount of spectrum in appropriate frequency bands;

i) that decisions on this matter should permit the operation of as many systems as possible;

MOD USA/12/203

j) that~~, in spite of the urgency attached to the development of such systems,~~ technical, operational and regulatory issues should be studied in order to achieve the most efficient use of the spectrum that may be available for these systems;

k) that there is a need for the provision of services on a competitive basis between GSO fixed-satellite service (FSS) and non-GSO FSS systems as well as between non-GSO FSS and non-GSO FSS systems;

l) that the Radio Regulations must be sufficiently flexible to accommodate the introduction and implementation of innovative technologies as they evolve, and allow the further development and implementation of any proposed system in conformity with their provisions,

considering further

MOD USA/12/204

a) that ~~further~~ITU-R has conducted technical, operational and regulatory studies ~~are required~~ in order to determine ~~further~~ the conditions under which sharing of the frequency bands 10-30 GHz which are allocated to the FSS and where ~~Resolution **46 (Rev.WRC-97)**~~No. **S9.11A** does not apply is feasible between GSO and non-GSO systems, ~~between non-GSO systems~~ and between non-GSO and terrestrial systems and other space systems;

Reasons: All but the deletion proposed in line 4 of *considering further a)* are from the CPM Report; deletion of "between non-GSO systems" is necessary because past-tense reference to non-GSO/non-GSO studies is incorrect.

SUP USA/12/205

~~*b)* that it is likely that non-GSO FSS systems communicated to the Radiocommunication Bureau will not be brought into use before the WRC-99;~~

Reasons: Transitional measure that is no longer required.

MOD USA/12/206

~~c~~b) that the diverging interpretations arising from No. **S22.2** result in an ambiguous regulatory status for both existing and future GSO and non-GSO systems in the FSS in the bands where this provision applies, with consequential risks for both types of systems;

~~d~~c) that the harmonious development of non-GSO and GSO systems in the FSS requires that these ambiguities be resolved ~~with no further delay~~in bands subject to No. **S22.2** where non-GSO FSS systems have been proposed;

Reasons: Clarification.

MOD USA/12/207

~~e~~d) that in resolving these ambiguities in the bands referred to in *resolves* 1 below, the GSO arc must be protected to ensure continued use of existing FSS systems and the development of new GSO technologies and systems in both non-planned bands and bands where plans exist;

SUP USA/12/208

~~*f)* that these ambiguities may be resolved in certain frequency bands by adopting power flux-density (pfd) limits which would apply to non-GSO FSS systems to protect GSO FSS systems, and by including in Article **S22** limits on the power radiated by non-GSO FSS systems in order adequately to protect GSO FSS systems in the frequency bands and sharing situations where Resolution **46 (Rev.WRC-97)** does not apply;~~

Reasons: This aspect has already been addressed in the review of the power limits conducted in advance of WRC-2000, and has not been shown to apply in any other bands. *Considering further f)* below covers the situation.

MOD USA/12/209

~~g~~e) that in certain frequency bands which are currently used or planned to be used extensively by GSO FSS systems, ~~provisional~~ power flux-density limits applicable to non-GSO FSS systems have been developed;

MOD USA/12/210

~~h~~f) that non-GSO FSS systems have been proposed in some of these bands which could meet ~~these limits~~the limits in Tables **S22-1A**, **S22-1B**, **S22-1C**, **S22-2**, **S22-3**, **S22-4A** and **S22-4B** and would not require specific protection from existing and future GSO FSS systems, provided that minimum constraints are applied to GSO FSS systems, such as off-axis earth station e.i.r.p. limits;

Reasons: Clarification of which limits can be met by the proposed non-GSO FSS systems.

MOD USA/12/211

~~i~~g) that in the bands where the limits referred to in *considering further ~~f), g)~~* ~~and~~ *~~h~~* ~~would~~ *e)* and *f)* apply, there ~~would be~~is no need for a coordination procedure between non-GSO FSS and GSO systems, with the exception of coordination between earth stations operating in opposite directions of transmission and coordination with earth stations using very large antennas;

MOD USA/12/212

~~j~~h) that there ~~would be~~is a need for a coordination procedure between non-GSO systems in the FSS and between non-GSO FSS systems and non-GSO systems in other services and for specific sharing criteria associated with this procedure, taking into consideration various types of non-GSO systems, including those in highly elliptical orbits;

SUP USA/12/213

~~*k)* the need to protect other co-primary services having allocations in the frequency bands referred to in *considering further a)* above and the need to assess further the sharing conditions between non-GSO FSS systems and these services;~~

Reasons: This has already been taken care of for the studied 10-30 GHz band, and would not apply with regard to non-GSO/non-GSO FSS studies in those bands.

MOD USA/12/214

~~l~~i) that further studies on sharing conditions in frequency bands other than the 10-30 GHz frequency bands~~,~~, where non-GSO FSS systems have been proposed, where ~~Resolution **46 (Rev.WRC-97)**~~No. **S9.11A** does not apply, and where Article **S22** does not include limits for non-GSO FSS systems, may also be necessary on the basis of the requirements that may emerge,

Reasons: Clarification. With the exception of those *considering/considering further* with reasons below them, all changes other than to numbering are as recommended in Annex 5 to Chapter 3 of the Report of CPM-99-2. In *considering further* with reasons below them, only noted changes are different from what was recommended by the CPM.

noting

1 that information relating to GSO and non-GSO systems in the FSS in the 10-30 GHz bands has been communicated to the Bureau;

2 that some of these systems are in operation and others will be operated in the near future and, consequently, difficulties may be experienced in modifying their characteristics;

3 the need to protect existing and future terrestrial and space services and systems;

4 that No. **S22.2** is an operational provision which is to be applied between administrations, and does not require any specific action or finding by the Bureau,

recognizing

that the geostationary-satellite orbit and its associated spectrum are a uniquely valuable resource and that equitable access to this resource needs to be protected for all countries in the world,

ADD USA/12/215

further recognizing

that methods of calculating aggregate additional operational limits for protection of 3 m and 10 m earth stations in the bands 10.7-12.75 GHz requires further study,

SUP USA/12/216

resolves

~~1 that, as of 22 November 1997, in the frequency bands specified in Tables **S22-3** and **S22-4** of Article **S22**, and in Tables 1 and 2 in Annex 1 to this Resolution, non-GSO FSS systems shall apply the procedures of Section I of Article **S9**, Nos. **S9.17** and **S9.17A**/Sections I and III of Article **11** and the procedures of Article **S11/13**, and the non-GSO FSS systems for which complete notification information has been received by the Bureau after 21 November 1997 shall be subject to the provisional power limits in Article **S22** and in Annex 1 to this Resolution;~~

Reasons: This provision can be suppressed, as it is included within Example Radio Regulation No. **S22.5F** as agreed and included in Annex 1 to Chapter 3 to the Report of CPM-99-2 (see also proposal IAP/14/263).

SUP USA/12/217

~~2 that these limits shall be applied provisionally until the end of WRC-99, and that non-GSO FSS systems for which complete notification information has been received by the Bureau after 21 November 1997 shall be subject to the power limits in Article **S22**, as revised, if appropriate, by WRC-99;~~

Reasons: This provision is a transitional measure that is no longer required after WRC-2000.

SUP USA/12/218

~~3 that, as of 22 November 1997, in applying No. **S22.2,** administrations may consider these provisional power limits as corresponding to permissible levels of interference from a non-GSO system into a GSO system, irrespective of the dates of receipt by the Bureau of the complete notification information relating for the non-GSO system and of the complete coordination information for the GSO network;~~

Reasons: This provision is a transitional measure that is no longer required after WRC-2000.

SUP USA/12/219

~~4 that, as of the end of WRC-99, an administration operating a non-GSO FSS system which is in compliance with the limits in Article **S22**, as revised, if appropriate, by WRC-99, shall be considered as having fulfilled its obligations under No. **S22.2** with respect to any GSO network, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO system and of the complete coordination information for the GSO network;~~

Reasons: This provision can be suppressed, as it is included within Example Radio Regulation No. **S22.5G** as agreed and included in Annex 1 to Chapter 3 to the report of CPM-99-2 (see also Proposal IAP/14/264).

SUP USA/12/220

~~5 that, as of the end of WRC-99, in the frequency bands specified in No. **S22.29** and § 2.4 of Annex 1 to this Resolution, GSO FSS systems for which complete coordination information has been received by the Bureau after the end of WRC-99 shall be subject to the limits in Article **S22** and in § 2.1, 2.2 and 2.3 of Annex 1 to this Resolution, as revised, if appropriate, by WRC-99;~~

Reasons: This provision must be suppressed, as the United States proposal (contained in USA/12/184 to 185) is to modify No. S22.26 and suppress Nos. S22.27 to S22.29, so that there are no off-axis e.i.r.p. density limits for FSS systems contained in S22 as of the end of WRC-2000 under this provision.

MOD USA/12/221

~~6~~1 that, as of 22 November 1997, in the frequency bands specified in ~~No. **S22.29** and Tables 1 and 2 of Annex 1 to this Resolution~~Tables **S22-1A**, **S22-1B**, **S22-1C** and **S22-2**, non-GSO systems shall not claim protection from GSO networks in the FSS operating in accordance with the Radio Regulations, irrespective of the dates of receipt by the Bureau of the complete notification information for the non-GSO FSS systems and of the complete coordination information for the GSO networks;

Reasons: *Resolves* 6 from Resolution 130 (renumbered here as *resolves* 1) is an essential provision that is not dependent on the establishment of minimum constraints on GSO FSS systems. The United States is also proposing to retain this measure permanently in the Radio Regulations (see Document WRC2000/12(Add.11)).

MOD USA/12/222

~~6~~1.1 that, in the case that, between 22 November 1997 and the end of WRC-~~99~~2000, if an administration operating or bringing into use a GSO FSS system before the end of WRC-~~99~~2000, because it consider~~s~~ed that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system, ~~then:~~

MOD USA/12/223

~~6.1.1 the administration operating the GSO system shall send~~sent to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based~~,~~ and if this is not resolved by the end of WRC-2000, then:

MOD USA/12/224

~~6.1.2~~1.1.1 in the bands from 10.7 GHz to 14.5 GHz, unless the limits adopted by WRC-2000 are met, the administration operating the non-GSO FSS system shall resolve the difficulties,

MOD USA/12/225

~~6.1.3~~1.1.2 in the bands 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space) and 29.5-30.0 GHz (Earth-to-space), unless the limits adopted by WRC-2000 are met, the administrations concerned shall make every possible effort to resolve the difficulties by means of mutually acceptable adjustments to their networks;

Reasons: Although the provisions of *resolves* 6.1 must, by their terms, have been invoked prior to the end of WRC-2000, the actions contemplated by *resolves* 6.1.2 and 6.1.3 could extend beyond the end of WRC-2000. Thus, it is necessary to retain a suitably modified *resolves* 6.1, 6.1.1, 6.1.2, and 6.1.3. If this *resolves* has not been invoked by the end of WRC-2000, WRC-2000 may consider its suppression.

MOD USA/12/226

~~7~~2 that, if an administration bringing into use a GSO FSS system after the end of WRC-~~99~~2000 considers that a non-GSO FSS system proposed by another administration and which complies with the limits in Article **S22**~~, as revised, if appropriate, by WRC-99,~~ might cause unacceptable interference into its GSO system, the administrations concerned shall make every possible effort to resolve the difficulties by means of mutually acceptable adjustments to their networks~~;~~.

Reasons: This *resolves* should be retained to encourage good faith efforts by administrations operating GSO FSS and non-GSO FSS systems with regard to protection of future GSO FSS operations.

SUP USA/12/227

~~8 that, as of 22 November 1997, non-GSO systems in the FSS in the frequency bands referred to in *resolves* 1 above, shall, for coordination with other non-GSO FSS systems, be subject to application of the provisions of § 2.1 of Section II of Resolution **46 (Rev.WRC-97)**/No. **S9.12**,~~

requests ITU-R

MOD USA/12/228

1[1] ~~taking into account *considering further a)*,~~ to conduct and complete, as a matter of urgency, ~~and complete, in time for consideration by WRC-99:~~the studies, in the frequency bands specified in Tables **S22-1A, S22-1B, S22-1C** and **S22-2,** relating to the sharing criteria to be applied during the coordination between non-GSO FSS systems where No. **S9.10** applies, with a view to promoting efficient use of spectrum/orbit resources and equitable access to these resources by all countries;

MOD USA/12/229

[1] See Annex ~~2~~1 for further details concerning specific aspects of these studies in relation to frequency sharing between systems in the non-GSO FSS and the GSO FSS.

SUP USA/12/230

~~1.1 the appropriate technical, operational and regulatory studies to review the regulatory conditions relating to the coexistence of non-GSO and GSO systems in the FSS, in order to ensure that they do not impose undue constraints on the development of non-GSO and GSO FSS systems;~~

SUP USA/12/231

~~1.2 the development of a methodology for calculating the power levels produced by non-GSO FSS systems and the compliance of these levels with the limits referred to in *resolves* 1 and 2 above;~~

1.3 the studies relating to the sharing criteria to be applied for determining the need for coordination between non-GSO FSS systems and the need for coordination between terrestrial services and non-GSO systems in the FSS and in other space services, with a view to promoting efficient use of spectrum/orbit resources and equitable access to these resources by all countries;

Formatted

ADD USA/12/232

2 to conduct further study of the aggregate $epfd_{down}$ limits and associated percentages of time for the 3 m and 10 m GSO FSS earth station antennas from Resolution **WWW (WRC-2000)**, Table WWW-1A, to determine whether the aggregate interference caused by all co-frequency non-GSO FSS systems in the subject bands into GSO FSS systems exceeds the maximum interference levels that are necessary to protect these GSO systems (see Annex 2);

ADD USA/12/233

3 to develop methods of calculating aggregate additional operational limits for the protection of 3 m and 10 m earth stations in the bands 10.7-12.75 GHz;

MOD USA/12/234

~~2~~4[1] ~~taking into account *considering further l)*, to undertake the development~~to conduct the appropriate technical, operational and regulatory studies towards the possible development of power limits or other frequency sharing mechanisms among GSO, non-GSO and terrestrial systems in ~~the~~ frequency bands other than those referred to in ~~*resolves*~~*requests ITU-R* 1 above, where No. **S9.11A** does not apply, ~~and~~ where non-GSO FSS systems ~~are likely to be implemented~~have been proposed, and where GSO FSS systems are used or expected to be used ~~extensively~~,

MOD USA/12/229

[1] See Annex ~~2~~1 for further details concerning specific aspects of these studies in relation to frequency sharing between systems in the non-GSO FSS and the GSO FSS.

Reasons: Modifications to *requests ITU-R* 1 are a streamlined version of recommended change from the CPM Report. Certain material from the CPM recommendation has already been addressed in the 10-30 GHz band, and need not be further studied. Modifications to *requests ITU-R* 2 and suppression of *requests ITU-R* 1.1 and 1.2 are slightly modified from that recommended in Annex 5 to Chapter 3 of the Report of CPM-99-2 to focus the scope of the studies that may be conducted in response to *requests ITU-R* 2.

instructs the Radiocommunication Bureau

MOD USA/12/235

1 as of the end of WRC-~~99~~2000, to review and, if appropriate, revise, any finding previously made on the compliance with the limits contained in Article **S22** of a non-GSO FSS system for which complete notification or coordination information, as appropriate, has been received between 22 November 1997 and the end of WRC-~~99~~2000. This review shall be based on the values in Article **S22**, as revised~~, if appropriate,~~ by WRC-~~99.~~2000;

ADD USA/12/236

2 that, between 22 November 1997 and 2 June 2000, non-GSO systems in the FSS in the frequency bands referred to in *resolves* 1 above, shall, for coordination with other non-GSO FSS systems, be subject to application of the provisions of No. **S9.12**;

Reasons: This is consequential to proposing non-GSO/non-GSO FSS coordination pursuant to a new Radio Regulation No. S9.10 as of 2 June 2000 (IAP proposal IAP/14/273 (ADD S9.10)).

ADD USA/12/237

3 to report to WRC-03 the results of studies under *requests ITU-R* 1, 2, 3 and 4.

SUP USA/12/238

~~ANNEX 1 TO RESOLUTION 130 (WRC-97)~~

~~**Provisional limits**~~

Reasons: Suppression of Annex 1 is as recommended in Annex 5 to Chapter 3 of the Report of CPM-99-2.

MOD USA/12/239

ANNEX ~~2~~1 TO RESOLUTION 130 (Rev.WRC-~~97~~2000)

ITU-R studies on frequency sharing between non-GSO FSS and GSO FSS

The following is a list of the studies and related activities required.

SUP USA/12/240

~~1 Characterization of short-duration interference peaks which might exceed equivalent pfd limits set by a world radiocommunication conference for large earth station antennas, in terms of maximum and mean amplitudes, maximum and mean durations, mean time between occurrences, aggregate percentages of time of occurrences and typical amplitude/time profiles.~~

MOD USA/12/241

~~2~~1 Acquisition of data relating to the impact of the interference peaks on the performance of a range of earth station demodulators of various types and origins.~~ Administrations are encouraged to cooperate in this matter by arranging for the appropriate measurements to be carried out, and submitting the results to the appropriate working parties or task groups in time to be included in the ITU-R report to the next conference.~~

MOD USA/12/242

~~3~~2 ~~Carrying out computer simulations to determine the impact on equivalent pfd statistics of multiple non-GSO networks interfering with a GSO downlink, and in particular to discover the percentage-of-time thresholds for which the probability of simultaneous interference peaks from satellites in different non-GSO constellations becomes significant. Both homogeneous and inhomogeneous sets of non-GSO systems should be simulated where the necessary data are available.~~Identify the parameters and appropriate assumptions necessary to calculate pfd statistics from multiple non-GSO FSS systems into a GSO earth station. Calculate and compare aggregate pfd statistics using various modelling options including full simulation, a modified pfd mask (ITU-R Document 11/153), and convolution. Determine the number and location of GSO earth station test points required to accurately characterize the aggregate interference.

SUP USA/12/243

~~4 Conducting investigations to find out whether the emissions from the satellites and earth stations of non-GSO systems would cause problems for the tracking, telemetry and command of GSO (and non-GSO) satellites, during both their launch and operational phases, and the development of methods for avoiding such problems.~~

MOD USA/12/244

~~5~~3 Carrying out computer simulations to derive the time statistics of short-term interference between two or more non-GSO FSS networks, with the objective of determining ~~the approximate number of such networks which could co-exist in the same bands~~how such networks could co-exist.

SUP USA/12/245

~~6 Identification and validation of software which could be used by the Bureau to check whether a system for which an application for spectrum has been made would comply with the equivalent pfd and aggregate pfd limits.~~

MOD USA/12/246

~~7~~4 Carrying out studies to determine the feasibility of frequency sharing between non-GSO FSS networks using circular orbits and ~~networks using slightly-inclined geostationary orbits, and also between~~ non-GSO FSS networks ~~and networks~~ using ~~"quasi-geostationary"~~non-circular orbits.

SUP USA/12/247

~~8 Development, if practicable, of continuous curves of equivalent pfd versus antenna diameter and/or *G/T* of the GSO earth station to be protected. Whilst it may be necessary to limit the compliance checking by the Bureau to a few discrete antenna sizes, administrations will need to know that the protection will be adequate in the case of antennas of other sizes; hence the desirability of continuous curves.~~

MOD USA/12/248

~~9~~5 Continuation of studies on techniques for the mitigation of interference ~~between GSO and non-GSO networks, and between~~amongst non-GSO networks.

SUP USA/12/249

~~10 Refinement of the methodologies in Recommendation ITU-R S.1323 for the derivation of *I/N* limits and their conversion to equivalent pfd and aggregate pfd limits, taking into account propagation fade statistics, the different circumstances of "transparent" and remodulating satellite transponders, and the impact of fade counter-measures such as adaptive power control.~~

SUP USA/12/250

~~11 Consideration of how account can be taken, in studies concerning the definition of uplink limits, of the gain versus off-axis angle characteristics of the receiving spot beams of geostationary satellites.~~

SUP USA/12/251

~~12 Taking into account that the bands allocated to the FSS are used by the fixed, radiolocation and space science services, study of the criteria for sharing between non-GSO FSS and GSO FSS systems and systems in those services.~~

Reasons: Certain of the studies ordered in Annex 2 to Resolution 130 (WRC-97) remain valid in the modified version of Resolution 130 that will be adopted by WRC-2000. Retention of a modified annex will help facilitate the work of ITU-R.

ADD USA/12/252

ANNEX 2 TO RESOLUTION 130 (Rev.WRC-2000)

Further study is required of the aggregate $epfd_{down}$ limits and associated percentages of time for the 3 m and 10 m GSO FSS earth station antennas from Resolution WWW (WRC-2000), Table WWW-1A, to determine whether the aggregate interference caused by all co-frequency non-GSO FSS systems in the subject bands into GSO FSS systems exceeds the maximum interference levels that are necessary to protect these GSO systems.

Reasons: Consequential to the addition of *requests ITU-R* 2. See also *further recognizing* from IAP/14/287 (Resolution **WWW (WRC-2000)**).

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 10 to
Document 12-E
11 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.13.1 - on the basis of the results of the studies in accordance with Resolutions 130 (WRC-97), 131 (WRC-97) and 538 (WRC-97): to review and, if appropriate, revise the power limits appearing in Articles S21 and S22 in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services

Incorporation of certain provisions of Resolutions 130 (WRC-97) and 538 (WRC-97) into Article S5

Proposed modifications to Article S5

Background information

The following are proposals to modify footnotes in Article S5 to reflect certain provisions of Resolutions 130 and 538. These proposals are based on Option 1A in Annex 6 to Chapter 3 of the CPM Report.

Proposals

MOD USA/12/197

S5.520 The use of the band 18.1-18.4 GHz by the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service using the geostationary-satellite orbit.

Formatted

Reasons: Since studies have not been undertaken by ITU-R on the potential interference to FSS or fixed service receiving stations from non-GSO FSS (Earth-to-space) operations in the band 18.1-18.4 GHz, the footnote is modified to limit use of the band in the Earth-to-space direction to GSO systems.

MOD USA/12/198

S5.441 The use of the bands 4 500-4 800 MHz (space-to-Earth), 6 725-7 025 MHz (Earth-to-space) by the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by geostationary-satellite systems in the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7-10.95 GHz (space-to-Earth), 11.2-11.45 GHz (space-to-Earth) and 12.75-13.25 GHz (Earth-to-space) by a non-geostationary-satellite system~~s~~ in the fixed-satellite service ~~shall be in accordance with the provisions of Resolution **130 (WRC-97)**~~is subject to the application of the provisions of MOD **S9.10** for coordination with other non-geostationary-satellite systems in the fixed-satellite service. In these bands, non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service. The provisions of Resolution **130 (Rev.WRC-2000)** apply.

MOD USA/12/199

S5.484A The use of the bands 10.95-11.2 GHz (space-to-Earth), 11.45-11.7 GHz (space-to-Earth), 11.7-12.2 GHz (space-to-Earth) in Region 2, 12.2-12.75 GHz (space-to-Earth) in Region 3, 12.5-12.75 GHz (space-to-Earth) in Region 1, 13.75-14.5 GHz (Earth-to-space), 17.8-18.6 GHz (space-to-Earth), 19.7-20.2 GHz (space-to-Earth), 27.5-28.6 GHz (Earth-to-space), 29.5-30 GHz (Earth-to-space) by a non-geostationary~~- and geostationary-~~satellite system~~s~~ in the fixed-satellite service is subject to application of the provisions of ~~Resolution **130 (WRC-97)**. The use of the band 17.8-18.1 GHz (space-to-Earth) by non-geostationary fixed-satellite service systems is also subject to the provisions of Resolution **538 (WRC-97)**~~MOD **S9.10** for coordination with other non-geostationary-satellite systems in the fixed-satellite service. In these bands, non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service. The provisions of Resolution 130 **(Rev.WRC-2000)** apply.

MOD USA/12/200

S5.487A *Additional allocation:* in Region 1, the band 11.7-12.5 GHz, in Region 2, the band 12.2-12.7 GHz and, in Region 3, the band 11.7-12.2 GHz, are also allocated to the fixed-satellite service (space-to-Earth) on a primary basis, limited to non-geostationary systems and subject to the application of the provisions of ~~Resolution **538 (WRC-97)**~~MOD **S9.10** for coordination between non-geostationary-satellite systems in the fixed-satellite service. In these bands, non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from GSO networks in the broadcasting-satellite service. The provisions of Resolution **538 (Rev.WRC-2000)** apply.

MOD USA/12/201

S5.516 The use of the band 17.3-18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3-17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2-12.7 GHz, see Article **S11**. The use of the bands 17.3-18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8-18.1 GHz (Earth-to-space) in Region 2 by non-geostationary-satellite systems in the fixed-satellite service is subject to the application of the provisions of ~~Resolution **538 (WRC-97)**~~MOD **S9.10** for coordination between non-geostationary-satellite systems in the fixed-satellite service. In these bands, non-geostationary-satellite systems in the fixed-satellite service shall not claim protection from geostationary-satellite networks in the fixed-satellite service. The use of the band 17.3-17.8 GHz in Region 2 by systems in the fixed-satellite service (Earth-to-space) is limited to geostationary satellites. The provisions of Resolution **538 (Rev.WRC-2000)** apply.

Reasons: These modifications to Article S5 are to replace the references to Resolutions 130 and 538 with references to MOD S9.10 in Article S9. Additional text on No. S5.516 is needed to clarify the intent that there is no allocation in the band 17.3-17.8 GHz in Region 2 for non-GSO FSS (Earth-to-space). The possibility of an allocation was to be based on sharing studies between the non-GSO FSS and the existing and planned services. Studies show that sharing between radiolocation stations and non-GSO FSS networks and non-GSO FSS networks is not feasible due to severe interference from operational radiolocation stations and these services are not compatible.

Formatted
Formatted
Formatted
Formatted
Formatted

In addition, the band 17.3-17.8 GHz in Region 2 is allocated to BSS beginning 1 April 2007. Studies show that transmit non-GSO FSS earth stations are not compatible with receive BSS earth stations.

In addition, as a result of expected changes to Resolutions 130 and 538 at WRC-2000, these modifications to footnotes contained in Article S5 will be needed to incorporate the appropriate *resolves* of Resolutions 130 (WRC-97) and 538 (WRC-97) into the Radio Regulations.

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.13.1 - on the basis of the results of the studies in accordance with Resolutions 130 (WRC-97), 131 (WRC-97) and 538 (WRC-97): to review and, if appropriate, revise the power limits appearing in Articles S21 and S22 in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services

Off-axis e.i.r.p. limits applicable to GSO FSS systems in the frequency bands 12.75-13.25 GHz, 13.75-14.50 GHz and 29.5-30 GHz

Proposed modifications to Section VI of Article S22

Background information

WRC-97 adopted, then suspended, FSS earth station off-axis e.i.r.p. density limits in the 12.75-13.25 GHz, 13.75-14.0 GHz and 14.0-14.5 GHz (Earth-to-space) bands to facilitate sharing between non-GSO FSS and GSO FSS systems in these frequency bands. These limits were immediately suspended because it was recognized that they were developed for the GSO/GSO FSS sharing environment and, if applied to the GSO/non-GSO FSS sharing environment, may unduly constrain certain GSO FSS operations. The impact of these limits on older GSO FSS earth stations also needed further study.

ITU-R studied this issue and concluded that some existing or future GSO FSS earth stations may exhibit off-axis e.i.r.p. density levels higher than those specified in Recommendation ITU-R S.524, *Maximum permissible levels of off-axis e.i.r.p. density from earth stations in GSO networks operating in the fixed-satellite service transmitting in the 6, 14 and 30 GHz frequency bands,* in directions beyond ± 3 degrees of the geostationary arc due to off-set feeds and spillover effects. In recognition of this characteristic, it was agreed that Recommendation ITU-R S.524 should be modified to recommend GSO FSS earth station off-axis e.i.r.p. density levels beyond 3 degrees of the geostationary orbit which are 3 dB relaxed from the recommended levels within 3 degrees of the geostationary orbit (see Document 4A/TEMP/234). This would provide co-frequency non-GSO FSS systems with an upper bound to the level of interference that non-GSO FSS systems would need to tolerate from GSO FSS systems. The ITU-R studies did not address whether these maximum e.i.r.p. density levels were appropriate for inclusion in the Radio Regulations.

The CPM Report identified three options for how the revised off-axis e.i.r.p. limits could be considered by the Conference. Under Option 1, the Conference could suppress the current limits in Section VI of Article S22 of the Radio Regulations. Thus, no FSS earth station off-axis e.i.r.p. limits would be included in the Radio Regulations and Section VI of Article S22 could be modified to encourage administrations to use the latest ITU-R Recommendations, which was the case prior to WRC-97. Under Option 2, the Conference could modify Section VI of Article S22 to include the revised off-axis e.i.r.p. limits included in Chapter 3 of the CPM Report or the levels recommended in the most recent modification to Recommendation ITU-R S.524 (Document 4A/TEMP/234). Under Option 3, the Conference could modify Section VI of Article S22 to incorporate by reference off-axis e.i.r.p. limits included in a specific ITU-R Recommendation, e.g. modifications to Recommendation ITU-R S.524 approved at WP 4A meeting in February 2000.

Each of the three options has certain shortcomings. As noted in the CPM Report, the first option would not provide additional protection for non-GSO networks and it would not provide clear guidelines to non-GSO system designers. The second option could inhibit the flexibility of GSO FSS system designers by including in the Radio Regulations off-axis limits that could not be exceeded in the future for any reason. Finally, the third option may not be available to the WRC-2000 because, while ITU-R Working Party 4A has agreed on off-axis limits to be included in a modification to Recommendation ITU-R S.524, these modifications in the 12.75-13.25 GHz and 13.75-14.50 GHz frequency bands will not be finalized in time for consideration by WRC-2000.

ARTICLE S22

Space services[1]

MOD USA/12/183

Section VI – Earth station off-axis power limitations in the fixed-satellite service~~11~~

MOD USA/12/184

S22.26 § 9 ~~The level of equivalent isotropically radiated power (e.i.r.p.) emitted by an earth station shall not exceed the following values for any off-axis angle φ which is 2.5° or more off the main-lobe axis of an earth station antenna:~~The level of equivalent isotropically radiated power (e.i.r.p.) emitted by an earth station at angles in all directions off the main beam axis has a significant impact on interference caused to other geostationary satellite networks and non-geostationary satellite networks. Enhanced utilization and easier coordination would be attained by minimizing such off-axis radiation and administrations are encouraged to achieve the lowest values practicable bearing in mind the latest ITU-R Recommendations. Minimizing such levels is particularly important in intensively used uplink bands.

~~*Off-axis angle*~~	~~*Maximum e.i.r.p.*~~
~~2.5° ≤ φ ≤ 7°~~	~~(39 – 25 log φ) dB(W/40 kHz)~~

~~11 **S22.VI.1** The provisions of this section are suspended pending the review of the values in Nos. **S22.26**, **S22.27** and **S22.28** by WRC-99.~~

~~7° < φ ≤ 9.2°~~	~~18 dB(W/40 kHz)~~
~~9.2° < φ ≤ 48°~~	~~(42 – 25 log φ) dB(W/40 kHz)~~
~~48° < φ ≤ 180°~~	~~0 dB(W/40 kHz)~~

SUP USA/12/185

S22.27 to **S22.29**

Reasons: This proposal is a hybrid of Options 1 and 3 from Annex 7 to Chapter 3 of the CPM Report. Under the hybrid approach, sections S22.27 through S22.29 of Section VI of Article S22 would be suppressed. Additionally, section S22.26 would be modified to indicate that administrations operating GSO FSS networks should comply with the e.i.r.p. density levels contained in the appropriate Recommendation. The advantage to this approach is that, as technology evolves, it allows the ITU-R recommended levels to be assessed and modified within ITU-R in a timely manner. Further, it points administrations to the technical guidelines that have been developed within ITU-R. At the same time, it provides guidance to the non-GSO FSS designer on the level of interference from co-frequency GSO FSS systems that might be present.

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.13.1 - on the basis of the results of the studies in accordance with Resolutions 130 (WRC-97), 131 (WRC-97) and 538 (WRC-97): to review and, if appropriate, revise the power limits appearing in Articles S21 and S22 in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services

Methodologies for ensuring compliance with operational and additional operational $epfd_{down}$ limits

Background information

CPM-99, to facilitate introduction of non-GSO FSS systems while affording protection to GSO FSS and BSS, agreed to three types of $epfd_{down}$ limits. These are: validation limits, to be verified by the Radiocommunication Bureau using an agreed software tool; operational limits, to provide operational GSO earth stations protection from synchronization loss; and additional operational limits to ensure protection to operational 3 m and 10 m GSO FSS earth stations operating in the 10.7-12.75 GHz bands. The operational limits, which are single values for 100 per cent of the time, provide an opportunity for development of regulatory procedures to be implemented by BR which would afford GSO systems a means of redress in the event such limits are exceeded by non-GSO FSS systems. The additional operational limits are specified values associated with periods of time. Such limits, as with the operational limits, must be met in practice, by each non-GSO FSS system.

With regard to both the operational limits and the additional operational limits, ITU-R has initiated studies on how to ascertain whether these limits are exceeded. At the recent meeting of WP 4A (20-29 February, 2000), a preliminary draft new Recommendation was developed concerning measurement techniques which can be used to determine if the operational limits are exceeded into operating GSO earth stations. As for the additional operational limits, preliminary views of WP 4A are that such limits cannot be measured, but rather, a detailed computer simulation of an non-GSO FSS system, utilizing operational assumptions, including traffic distribution and beam loading is required. Work is continuing in both these areas. The proposed Resolution CEA (WRC-2000) was developed to address subject.

The CPM-99 Report also indicated the need for regulatory procedures to implement the operational and additional operational $epfd_{down}$ limits which identify non-GSO systems exceeding the operational/additional operational limits and ensure immediate reduction of the interference level to the operational/additional operational limits by any non-GSO system exceeding those limits. The proposed Resolution CEA (WRC-2000) and interim procedures were developed in response to this requirement.

ADD USA/12/182

RESOLUTION CEA (WRC-2000)

Development of methodologies for ensuring compliance by non-geostationary satellite systems in the fixed-satellite service in certain frequency bands with the operational $epfd_{down}$ and additional operational $epfd_{down}$limits in Article s22

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-2000 adopted a number of epfd limits that apply to non-geostationary satellite systems in the fixed-satellite service in certain frequency bands between 10.7 and 30.0 GHz;

b) that compliance with the validation epfd limits adopted by WRC-2000 will be verified by the Radiocommunication Bureau before a non-geostationary fixed-satellite service system would be eligible for a favourable finding under the procedures in Article **S11** of the Radio Regulations;

c) that the operational $epfd_{down}$ limits and additional operational $epfd_{down}$ limits adopted by WRC-2000 in No. **S22.5G** of the Radio Regulations and associated Tables **S22-4A** and **S22-4B** and footnote 3 to Table **S22-1D** apply only to operational non-geostationary fixed-satellite service systems, and compliance with these limits is not subject to validation by the Radiocommunication Bureau in order for a non-geostationary fixed-satellite service system to receive a favourable finding under the procedures in Article **S11** of the Radio Regulations;

d) that the operational $epfd_{down}$ limits and the additional operational $epfd_{down}$ limits provide protection from unacceptable interference to operational geostationary fixed-satellite service and broadcasting-satellite service networks from co-frequency non-geostationary fixed-satellite service systems in the subject frequency bands;

e) that administrations operating geostationary fixed-satellite service and/or broadcasting-satellite service networks in frequency bands where operational $epfd_{down}$ limits and/or additional operational $epfd_{down}$ limits have been established require reliable means of ascertaining that operational non-geostationary fixed-satellite service systems are in compliance with the applicable limits;

f) that administrations operating non-geostationary fixed-satellite service systems in frequency bands where operational $epfd_{down}$ limits and/or additional operational $epfd_{down}$ limits have been established require reliable means of ascertaining the validity of assertions from administrations operating geostationary fixed-satellite service and/or broadcasting-satellite service systems that a particular non-geostationary fixed-satellite service system is operating in violation of the applicable limits;

g) that studies within ITU-R are an appropriate means for developing the methodologies and/or associated assessment techniques that administrations may use to ascertain compliance by a non-geostationary fixed-satellite service system with the operational $epfd_{down}$ limits and additional operational $epfd_{down}$ limits,

recognizing

a) that geostationary satellite networks in the fixed-satellite service and broadcasting-satellite service are operational or will be operational in the frequency bands where operational $epfd_{down}$ limits and additional operational $epfd_{down}$ limits apply, and that non-geostationary fixed-satellite service systems subject to the limits are planned for operation in the same bands;

b) that No. **S22.5F** provides that a non-geostationary fixed-satellite service system for which complete notification or coordination information, as appropriate, has been received by the Bureau after 21 November 1997 shall be subject to the power limits in Article **S22,** as adopted by WRC-2000;

c) that pursuant to No. **S22.5G** of the Radio Regulations, any exceedance of the operational $epfd_{down}$ limits or additional operational $epfd_{down}$ limits by a non-geostationary fixed-satellite service system to which the limits apply is a violation of No. **S22.2** of the Radio Regulations;

d) that in view of the importance of the protection that the operational $epfd_{down}$ limits and additional operational $epfd_{down}$ limits are intended to provide to geostationary satellite networks, and because there is to be no validation by the Bureau of compliance with these limits, it is important to discourage violations of the operational $epfd_{down}$ limits and additional operational $epfd_{down}$ limits by a non-geostationary fixed-satellite service system; if a violation nevertheless occurs, it should be corrected in the most expeditious manner,

resolves to instruct ITU-R

1 to study as a matter of urgency, and develop in time for consideration by WRC-02/03, methodologies that will permit administrations operating geostationary fixed-satellite service, geostationary broadcasting-satellite service, or non-geostationary fixed-satellite service networks in the frequency bands to which the operational $epfd_{down}$ limits and/or additional operational $epfd_{down}$ limits in Article **S22** apply:

a) to assess the interference levels (through either measurement or simulation) that would be produced by non-geostationary fixed-satellite service systems in the same bands;

b) to ensure that non-geostationary fixed-satellite service systems comply with the applicable limits; and

c) to develop appropriate methods, such as software tools, to be used by administrations in determining whether a proposed non-geostationary fixed-satellite service system complies with the additional operational limits;

2 to develop, as a matter of urgency, an appropriate recommendation on a mechanism and format for administrations operating non-GSO FSS systems to make available their satellite ephemeris data and update such data on a regular basis.

Reasons: In keeping with the CPM-99 compromise with regard to the adoption of validation, operational, and additional operational limits, the ITU Radiocommunication Bureau (BR) will not check compliance with the operational and the additional operational limits. CPM-99, therefore, agreed that it is essential to develop, as a matter of urgency, Recommendations to permit administrations to check compliance with the operational and the additional operational limits (see section 3.1.2.4.8 of the CPM-99 Report). Resolution CEA (WRC-2000) is proposed in response to this requirement. This Resolution is intended to focus the studies carried out by ITU-R in order to assist administrations operating geostationary fixed-satellite service, geostationary broadcasting-satellite service, or non-geostationary fixed-satellite service networks in the frequency bands to which the operational $epfd_{down}$ limits and/or additional operational $epfd_{down}$ limits in apply.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 7 to
Document 12-E
17 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.13.1 - to review and, if appropriate, revise the power limits appearing in Articles S21 and S22 in relation to the sharing conditions among non-GSO FSS, GSO FSS, GSO broadcasting-satellite service (BSS), space sciences and terrestrial services, to ensure the feasibility of these power limits and that these limits do not impose undue constraints on the development of these systems and services

Modifications to Resolution 538 (WRC-97)

Background information

WRC-97 adopted an allocation to non-GSO FSS in the Appendix S30 BSS bands (11.7-12.5 GHz in Region 1, 11.7-12.2 GHz in Region 3 and 12.2-12.7 GHz in Region 2) (see S5.487A). WRC-97 also specified provisions in Resolution 538, including provisional epfd limits, to govern non-GSO FSS in the Appendix S30 BSS bands and associated feeder-link bands (17.3-17.8 GHz in Regions 1 and 3, 17.8-18.1 GHz in all Regions). As a consequence of the extensive studies carried out within ITU-R under agenda item 1.13, it is expected that WRC-2000 will adopt revised epfd limits in Article S22 for non-GSO FSS in these bands. Therefore, it is necessary to revisit the provisions of Resolution 538 to update them accordingly. Annex 5 to Chapter 3 of the CPM-99 Report provides examples of modifications to Resolution 538.

The following proposal modifies Resolution 538 to suppress provisions that CPM-99 proposed to contain elsewhere in the Radio Regulations or that are no longer needed. In addition, necessary provisions of Resolution 538 are maintained, such as requesting BR to review findings made for certain non-GSO FSS systems based on the expected revision of the Article S22 epfd limits.

Proposal

MOD USA/12/163

RESOLUTION 538 (WRC-~~97~~2000)

Use of the frequency bands covered by Appendices S30/30 and S30A/30A by non-geostationary-satellite systems in the fixed-satellite service

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

MOD USA/12/164

a) that provisional limits adopted by WRC-97 have been ~~established~~revised and included in Article **S22** ~~and in the Annex to this Resolution~~ to ensure that the interference caused by non-geostationary-satellite (non-GSO) systems in the fixed-satellite service (FSS) into assignments operated in conformity with the Appendices **S30** and **S30A** Plans is maintained within ~~negligible~~agreed levels;

NOC USA/12/165

b) that the integrity of the above-mentioned Plans and their future modifications is to be ensured;

c) that non-GSO systems should not be entered into those Plans and therefore should not apply the procedures associated with the Plans and should not be protected by those procedures;

MOD USA/12/166

d) that ~~this Conference has~~WRC-97 decided to introduce in Article **S5** a new allocation to the FSS in the frequency bands 11.7-12.5 GHz in Region 1, 12.2-12.7 GHz in Region 2 and 11.7-12.2 GHz in Region 3, limited to non-GSO FSS systems,

Reasons: Editorial and changes for clarity.

resolves

1

SUP USA/12/167

1.1

MOD USA/12/168

1.~~2~~1 that ~~such a system shall, as of the end WRC-99,~~a non-GSO FSS system operating in the frequency bands covered by Appendices **30** and **30A** shall comply with the limits specified in Article **S22**, as revised~~, if appropriate~~, by WRC-~~99~~2000, irrespective of the date of receipt of the complete coordination or notification information, as appropriate, relating to the non-GSO FSS system;

Formatted

Formatted

Reasons: *Resolves* 1.1 can be suppressed, as it is a provisional measure for operational non-GSO systems between WRC-97 and WRC-2000. Modification to 1.2 is required to maintain the decision of WRC-97 to ensure the protection of the BSS Plans by all non-GSO systems irrespective of filing date with BR. While the proposed provisions of Article S22 will take care of this for systems filed after WRC-97, *resolves* 1.2 addresses systems filed prior to the end of WRC-97. If it is determined that no systems were filed prior to the end of WRC-97, WRC-2000 may consider that this provision can be suppressed.

SUP USA/12/169

1.3

Reasons: This *resolves* can be suppressed, as it is included in Radio Regulation S22.5G (see Annex 1 to Chapter 3 of the CPM Report and proposal IAP/14/264).

SUP USA/12/170

1.4

Reasons: This *resolves* is now covered by the $epfd_{is}$ limits appearing in Table S22-3 and Radio Regulation S22.5G (see Annex 1 to Chapter 3 of the CPM Report and proposals IAP/14/258 and 264).

MOD USA/12/171

1.~~5~~2 that, in the case that, between 22 November 1997 and the end of WRC-~~99~~2000, ~~if~~ an administration operating or bringing into use a GSO system before the end of WRC-~~99~~2000, because it consider~~s~~ed that a non-GSO FSS system proposed by another administration might cause unacceptable interference into its GSO system~~, then~~:

– ~~the administration operating the GSO system shall send~~sent to the administration operating the non-GSO FSS system the technical details upon which its disagreement is based and, if this is not resolved by the end of WRC-2000, then;

– unless the limits adopted by WRC-2000 are met, the administration operating the non-GSO FSS system shall continue its efforts to resolve the difficulties, taking into account especially degradation of picture and sound quality or signal availability with regard to GSO systems in operation;

Reasons: Although the provisions of *resolves* 1 must have been invoked prior to the end of WRC-2000, the actions contemplated by this *resolves* could extend beyond the end of WRC-2000. Thus, it is necessary to retain this *resolves* in a suitably modified form. If this *resolves* has not been invoked by the end of WRC-2000, WRC-2000 may consider its suppression.

SUP USA/12/172

1.6

MOD USA/12/173

1.~~7~~3 that, as of 22 November 1997, such a system shall be subject, for the coordination with non-GSO systems, to the application of ~~the provisions of § 2.1 of Section II of Resolution **46 (Rev.WRC-97)**~~/No. **S9.12**;

Reasons: Although this provision is proposed to be included in a footnote in Article S5, it would then only apply after the end of WRC-2000. Therefore, it is necessary to maintain this provision to apply from 22 November 1997.

Formatted

MOD USA/12/174

1.~~8~~4 that, as of 22 November 1997, such a system shall apply, using an equivalent power flux-density threshold of –185.3 dB(W/m^2/4 kHz) for 99.7% of the time, calculated with the reference 90 cm diameter antenna pattern provided in Annex 5 of Appendix **S30** for Regions 1 and 3, the provisions of No. **S9.8**/Article 7 of Appendix **S30** with respect to assignments which appear in Article 11 of Appendix **S30** with the symbols AE or PE~~;~~.

Reasons: WRC-2000 may decide that this specific agreement from WRC-97 is no longer required and that this provision may be suppressed.

SUP USA/12/175

2

Reasons: By the end of WRC-2000, this provision will have been overtaken by events.

requests ITU-R

Addendum 6 to Document 12-E
17 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

Agenda item 1.6.1 - review of spectrum and regulatory issues for advanced mobile applications in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary

Use of high altitude platform stations in IMT-2000 terrestrial systems

Background information

This proposal addresses the option to use the high altitude platform stations (HAPS) for the delivery of terrestrial IMT-2000 within the bands that WARC-92 identified for terrestrial IMT-2000 in S5.388, subject to licensing, technical, sharing, coordination and implementation regulation by administrations. It addresses regulatory issues relating to HAPS in the context of IMT-2000 and is not related to the issue of providing more spectrum for the terrestrial component of IMT-2000.

A high altitude platform station (HAPS) is defined in S1.66A as “A station located on an object at an altitude of 20 to 50 km and at a specified, nominal, fixed point relative to the Earth”. Each HAPS deploys a multibeam antenna capable of projecting numerous spot beams within its coverage area. The Radio Regulations, under S4.15A, state, “Transmissions to or from high altitude platform stations shall be limited to bands specifically identified in Article S5”. The only bands currently identified for use by HAPS in Article S5 are in footnote S5.552A that states that “The allocation to the fixed service in the bands 47.2-47.5 GHz and 47.9-48.2 GHz is designated for use by high altitude platform stations. The use of the bands 47.2-47.5 GHz and 47.9-48.2 GHz is subject to the provisions in Resolution 122 (WRC-97)”.

ITU-R TG 8/1 completed extensive studies regarding the ability of HAPS to provide IMT-2000 services within Regions 1 and 3 using the bands 1 885-2 025 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz and within Region 2 using the bands 1 885-1 980 MHz and 2 110-2 160 MHz identified for advanced communications applications, including IMT-2000. These studies address, among other things, the ability of HAPS to coordinate and share with IMT-2000 stations operating in neighbouring administrations and with certain stations operating in other services in adjacent bands. Draft new Recommendation ITU-R M.[8/115], as approved by ITU-R Study Group 8 for adoption by correspondence, considers certain sharing and coordination requirements associated with the use of HAPS as a base station within a terrestrial IMT-2000 system. The proposed

Resolution HAPS (WRC-2000) provides minimum performance characteristics from draft new Recommendation ITU-R M.[8/115].

This proposal recognizes that in accordance with footnote MOD S5.388 and Resolution IMT (WRC-2000), administrations may use the bands identified for IMT-2000, including the bands noted herein, for stations of other primary services to which they were allocated.

As with all other types of base stations operating as a base station in an IMT-2000 system, the proposal also recognizes the need for additional future studies on the compatibility of HAPS operating as a base station in an IMT-2000 system and other stations operating in the same and adjacent frequency bands.

This proposal calls for a footnote in Article S5 of the Radio Regulations identifying HAPS as an optional method for the delivery within an IMT-2000 system in the frequency bands identified for Regions 1 and 3, the bands 1 885-2 025 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz and for Region 2, the bands 1 885-1 980 MHz and 2 110-2 160 MHz, identified for advanced communications applications, including IMT-2000, subject to Resolution HAPS (WRC-2000), Resolution IMT (WRC-2000) and national regulations.

Concerning the optional implementation of HAPS in an IMT-2000 system, the following regulatory changes are proposed:

MOD USA/12/160

1 710-2 170 MHz

ADD USA/12/161

S5.BBB In Regions 1 and 3, the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz, and in Region 2, the bands 1 885-1 980 MHz and 2 110-2 160 MHz, may be used by high altitude platform stations as base stations within an IMT-2000 system in accordance with Recommendation ITU-R IMT.RSPC, Resolution **HAPS (WRC-2000)** and Resolution **IMT (WRC-2000)**. These bands are allocated to the fixed, mobile and the mobile-satellite services, and the use by IMT-2000 applications using high altitude platform stations as an IMT-2000 base station in these bands is based on the equality of rights between all allocated radio services and does not establish priority of assignments in these bands among stations of the primary services to which they are allocated.

ADD USA/12/162

DRAFT RESOLUTION HAPS (WRC-2000)

Use of high altitude platform stations providing IMT-2000 in the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz in Regions 1 and 3 and 1 885-1 980 MHz and 2 110-2 160 MHz in Region 2

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WARC-92 identified the bands 1 885-2 025 MHz and 2 110-2 200 MHz, intended for use on a worldwide basis for IMT-2000, including the bands 1 980-2 010 MHz and 2 170-2 200 MHz for the satellite component of IMT-2000, in No. **S5.388**;

b) that a high altitude platform station (HAPS) is defined in S1.66A as "A station located on an object at an altitude of 20 to 50 km and at a specified, nominal, fixed point relative to the Earth";

c) that HAPS may offer a new means of providing IMT-2000 services with minimal network build out as it is capable to provide service to a large footprint together with a dense coverage;

d) that, in accordance with MOD **S5.388** and Resolution **IMT (WRC-2000)**, administrations may use the bands identified for IMT-2000, including the bands noted herein, for stations of other primary services to which they were allocated;

e) that these bands are allocated to the fixed, mobile and mobile-satellite services;

f) that ITU-R did not address sharing and coordination between HAPS and some existing systems, such as PCS and MMDS, currently operating in some administrations in the bands 1 885-2 025 MHz and 2 110-2 200 MHz;

g) that in accordance with **S5.BBB**, HAPS is allowed to be used as a base station of terrestrial IMT-2000 in the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz in Regions 1 and 3 and 1 885-1 980 MHz and 2 110-2 160 MHz in Region 2, which are allocated to the fixed, mobile and the mobile-satellite services. The use by high altitude platform stations as an IMT-2000 base station in these bands is based on the equality of rights between all allocated radio services and does not establish priority of assignments in these bands among stations of the primary services to which they are allocated,

resolves

1 that administrations wishing to implement HAPS within a terrestrial IMT-2000 system shall give due consideration to the minimum performance characteristics and operational conditions given in Recommendation ITU-R M.[8/115], in particular:

1.1 that for the purpose of protecting certain stations operating in neighbouring administrations from co-channel interference, administrations using HAPS as base stations to IMT-2000 shall use antennae that comply with the following antenna pattern:

$G(\psi) = G_m - 3(\psi/\psi_b)^2$	dBi	for	$0 \le \psi \le \psi_1$
$G(\psi) = G_m + L_N$	dBi	for	$\psi_1 < \psi \le \psi_2$
$G(\psi) = X - 60\log(\psi)$	dBi	for	$\psi_2 < \psi \le \psi_3$
$G(\psi) = L_F$	dBi	for	$\psi_3 < \psi \le 90°$

where:

$G(\psi)$: gain at the angle ψ from the main beam direction (dBi)

G_m: maximum gain in the main lobe (dBi)

ψ_b: one-half of the 3 dB beamwidth in the plane of interest (3 dB below G_m) (degrees)

L_N: near-in-side-lobe level in dB relative to the peak gain required by the system design, and has a maximum value of –25 dB

L_F: G_m - 73 dBi far side lobe level (dBi)

$\psi_1 = \psi_b \sqrt{-L_N/3}$	degrees
$\psi_2 = 3.745\ \psi_b$	degrees
$X = G_m + L_N + 60\log(\psi_2)$	dB
$\psi_3 = 10^{(X-L_F)/60}$	degrees

The 3 dB beamwidth ($2\psi_b$) is again estimated by:

$$(\psi_b)^2 = 7442/(10^{0.1Gm}) \text{ (in degrees}^2\text{)}$$

where G_m is the peak aperture gain (dBi);

1.2 that a HAPS operating as a base station to provide IMT-2000 shall not exceed a co-channel spectral power flux-density (spfd) level of –121.5 dB (W/(m^2/MHz)) on the Earth’s surface outside an administration’s borders unless agreed otherwise with the affected neighbouring administration, noting that this does not necessarily protect all stations operating in co-channel services;

1.3 that a HAPS operating as a base station to provide IMT-2000, in order to protect mobile earth stations of the satellite component of IMT-2000 from interference, shall not exceed an out-of-band spfd level of –165 dB (W/(m^2/4 kHz)) on the Earth’s surface in the bands 2 160-2 200 MHz in Region 2 and 2 170-2 200 MHz in Regions 1 and 3;

1.4 that a HAPS operating as a base station to provide IMT-2000, in order to protect fixed stations from interference, shall not exceed an out-of-band spfd level on the Earth’s surface in the bands 2 025-2 110 MHz of:

–165 dB(W/(m^2/MHz)) for angles of arrival (θ) less than 5° above the horizontal plane;

–165 + 1.75 (θ - 5) dB (W/(m^2 /MHz)) for angles of arrival between 5° and 25° above the horizontal plane; and

–130 dB(W/(m^2/MHz)) for angles of arrival between 25° and 90° above the horizontal plane,

invites ITU-R

to complete additional studies of HAPS sharing and coordination criteria with, between and into other systems in the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz in Regions 1 and 3 and 1 885-1 980 MHz and 2 110-2 160 in Region 2, and in adjacent bands,

further resolves

that ITU-R should expeditiously complete its studies, and at the next WRC, update ITU regarding HAPS sharing and coordination criteria with, between and into other systems in the bands 1 885-1 980 MHz, 2 010-2 025 MHz and 2 110-2 170 MHz in Regions 1 and 3 and 1 885-1 980 MHz and 2 110-2 160 MHz in Region 2, and in adjacent bands.

Reasons: Footnote S4.15A limits transmissions to and from HAPS to bands specifically identified in the Table of Frequency Allocations. The addition of S5.BBB to the Table of Frequency Allocations will provide administrations with the option to utilize HAPS for IMT-2000 services within the identified bands subject to the provisions of Resolution HAPS, Resolution IMT and national and international regulatory procedures and provisions.

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROPOSALS RELATING TO PP-98 RESOLUTIONS

Resolution 86, the Plenipotentiary Conference (Minneapolis, 1998)
- Improving the satellite coordination and notification process

Proposal to modify Appendix S5 to the Radio Regulations to implement, with respect to geostationary-satellite networks operating in the fixed-satellite service in certain frequency bands, a coordination threshold based on a predetermined coordination arc

Background information

The 1998 Plenipotentiary Conference agreed through Resolution 86 on the need for improved coordination and notification of satellite networks. While proposals are being made to this Conference for temporary measures to deal with the current backlog of coordination requests, there is a need to improve the process to make it more efficient and effective on a long-term basis.

Working Party 4A, at its February 2000 meeting, developed a draft new Recommendation that provides the technical basis for using a coordination arc in certain frequency bands as the primary means of identifying potentially affected GSO FSS networks for coordination with other GSO FSS networks. Working Party 4A also recognized that not all systems within the coordination arc would be affected. It was also recognized that some GSO FSS systems outside of the coordination arc might want to be included in coordination based upon a calculated increase in noise temperature greater than 6%.

The following modifications to Appendix S5 to the Radio Regulations would implement such a procedure:

MOD USA/12/159

TABLE S5-1

Technical conditions for coordination
(see Article **S9**)

Reference of Article S9	**Case**	**Frequency bands (and Region) of the service for which coordination is sought**	**Threshold/condition**	**Calculation method**	**Remarks**
No. **S9.7** GSO/GSO	A station in a satellite network using the geostationary-satellite orbit (GSO), in any space radiocommunication service, in a frequency band and in a Region where this service is not subject to a Plan, in respect of any other satellite network using that orbit, in any space radiocommunication service in a frequency band and in a Region where this service is not subject to a Plan, with the exception of the coordination between earth stations operating in the opposite direction of transmission	1)3 400-4 200 MHz and 5 850-6 725 MHz 2)10.95-11.2, 11.45-11.7, 11.7-12.2 (Region 2) 12.5-12.75 (Regions 1 and 3) 12.7-12.75 (Region 2) and 13.75-14.5 GHz	1)Any network in the fixed-satellite service with a space station within an orbital arc of ±10 degrees of the orbital position of a proposed network in the fixed-satellite service 2)Any network in the fixed-satellite service with a space station within an orbital arc of ±9 degrees of the orbital position of a proposed network in the fixed-satellite service		With respect to the bands in items 1, 2, and 3; coordination will be required with a network having an orbital position outside the arcs where the administration responsible for that network requests to be included in the coordination process and demonstrates that the threshold value for coordination calculated in accordance with Appendix **S8** exceeds 6% With respect to the bands in items 1, 2, and 3; coordination will not be required with a network having an orbital position inside the arcs where the administration requesting coordination or the

		3)17.7-20.2 GHz and 27.5-30 GHz	3)Any network in the fixed-satellite service with a space station within an orbital arc of ±8 degrees of the orbital position of a proposed network in the fixed-satellite service		administration responsible for an affected network demonstrates that the threshold value for coordination calculated in accordance with Appendix **S8** does not exceed 6%. A geostationary-satellite network that is the subject of such a demonstration would be considered a network for which coordination would need to be effected, until such time as the demonstration is agreed or confirmed between the concerned administrations
		4)All~~Any~~ frequency bands, other than those in items 1, 2 and 3, allocated to a space service, where this service is not subject to a Plan; and the bands in items 1), 2) and 3) where the radio service of the proposed network or affected networks is other than the fixed-satellite service	4)Value of $\Delta T/T$ exceeds 6%	4)Appendix **S8**	

Reasons: The 1998 Plenipotentiary Conference agreed through Resolution 86 on the need for improved coordination and notification of satellite networks. While proposals are being made to this Conference for temporary measures to deal with the current backlog of coordination requests, there is a need to improve the process to make it more efficient and effective on a long-term basis. This proposal provides a simplified method of identifying affected administrations by using a coordination arc in certain frequency bands as the primary means of identifying potentially affected GSO FSS networks for coordination with respect to other GSO FSS networks. It is recognized that not all systems within the coordination arc would be affected. It is also recognized that some GSO FSS systems outside of the coordination arc might want to be included in coordination based upon a calculated increase in noise temperature greater than 6%.

ITU **WRC-2000** WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 4 to*[*]
Document 12-E
6 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSAL FOR THE WORK OF THE CONFERENCE

PROPOSAL RELATING TO RESOLUTION 86, PLENIPOTENTIARY CONFERENCE (MINNEAPOLIS, 1998), S5.393 AND RESOLUTION 528

Background information

At WARC-92, allocations in the range 1-3 GHz were made for sound (audio) broadcasting from satellites. Different allocations were adopted for different regions of the world. The band 2 310-2 360 MHz is allocated to the United States, Mexico and India for this purpose through footnote S5.393. Resolution 86 calls for improving the methods to facilitate the coordination of satellite networks.

As implementation of the 2 310-2 360 MHz band has proceeded, Resolution 528, as applied through footnote S5.393, has proved to be a hindrance to effective coordination of systems that would utilize frequencies in different parts of the entire allocation. Specifically, as a consequence of *resolves* 3, the two countries in Region 2 have encountered unnecessary difficulties in implementing their respective systems due to the 25 MHz restriction.

Given that there are only three countries in the footnote and only two countries named in Region 2, the planning aspect of Resolution 528 is not realistic for this band. Furthermore, the coordination of sound BSS and the complementary terrestrial component is covered by footnote S5.396. Consequently, the proposal is to suppress reference to Resolution 528 in footnote S5.393.

MOD USA/12/158

S5.393 *Additional allocation:* in the United States, India and Mexico, the band 2 310-2 360 MHz is also allocated to the broadcasting-satellite service (sound) and complementary terrestrial sound broadcasting service on a primary basis. Such use is limited to digital audio broadcasting~~ and is subject to the provisions of Resolution **528 (WARC-92)**~~.

[*] Pursuant to Resolution 26 (Rev.WRC-97) the Secretariat notes that this contribution was received on 17 April 2000.

Reasons: Resolution 528 unnecessarily limits the use of the entire resource of the full allocation available to the three countries indicated in this provision. Given the number of countries involved in S5.393, the reference to the Resolution is not necessary. Further, the requirement to coordinate under Resolution 33 remains applicable through S5.396. Therefore, reference to Resolution 528 can be suppressed.

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROPOSAL FOR TERRESTRIAL AND SATELLITE COMPONENTS OF IMT-2000

Agenda item 1.6.1 - review of spectrum and regulatory issues for advanced mobile application in the context of IMT-2000, noting that there is an urgent need to provide more spectrum for the terrestrial component of such applications and that priority should be given to terrestrial mobile spectrum needs, and adjustments to the Table of Frequency Allocations as necessary

Executive summary

The following proposal identifies bands to be considered by administrations for use for IMT-2000 and other advanced communication applications. “Advanced communication applications” include wireless systems and devices that provide high quality voice, data and/or video uses. This concept recognizes that there will be uses of the identified spectrum that are developed in response to market demands and technological advances. The proposal includes a modification to RR S5.388 and associated modifications to the Table of Frequency Allocations. Furthermore, it includes two supporting resolutions.

This proposal contains the following key characteristics:

1) identifies the bands 698-960 MHz, 1 525-1 559 MHz, 1 610-1 660.5 MHz, 1 710-2 025 MHz, 2 110-2 200 MHz and 2 483.5-2 690 MHz that encompass the terrestrial and satellite components of IMT-2000 and other advanced communication applications;

2) emphasizes that administrations have the flexibility to make their decisions regarding implementation of these bands, or portions thereof, based on their requirements and current uses;

3) identifies bands that are inclusive of the major bands being considered around the world, thereby increasing the possibility of global harmonization and international consensus;

4) amends original footnote S5.388 to clearly identify and provide equal treatment of all bands for IMT-2000 and other advanced communication applications in a single reference;

5) encourages the evolution of current technology and the freedom of service providers to select technology given market demands;

6) modifies S5.388 to emphasize that this footnote does not affect the regulatory priority of allocated services;

7) recognizes the need of many administrations to continue to study these bands for possible use for IMT-2000 and other advanced communication applications, to expeditiously complete these national studies, and to report the results of those studies and national decisions to ITU-R;

8) invites ITU-R to perform key studies and maintain a database of national studies and decisions on selection of spectrum for IMT-2000 and other advanced communication systems.

Background

The United States supports the development and implementation of IMT-2000 and other advanced communication applications and technologies. These applications will serve as critical components of the communications and information infrastructure of the future.

Over the past decade, the use of cellular-type personal mobile communications services has grown tremendously worldwide. Studies in ITU and elsewhere indicate that this growth in personal communications will likely continue and additional spectrum will be needed to accommodate this growth. Moreover, many administrations that initially introduced analogue-based services in certain bands are transitioning those services to digital technology. To facilitate the continued growth of IMT-2000 and other advanced communication applications, it is essential to provide a domestic regulatory framework that allows operators to transition easily from existing analogue and digital systems to IMT-2000 and other advanced communication applications.

The significant market demand for wireless and mobile access to new multimedia services and to the Internet further increases the need for additional spectrum for IMT-2000 and other advanced communication applications. By providing spectrum that can be used for a variety of wireless Internet applications, administrations have the opportunity to address many societal needs. This new spectrum can be used for providing Internet access to rural, sparsely populated or hard to reach areas, providing high data rate services to support tele-medicine and tele-education applications, in addition to providing a variety of new services and wireless devices for businesses and consumers.

Discussion

The United States proposes the identification of spectrum in several bands for consideration by administrations for the implementation of IMT-2000 and other advanced communication applications. Specifically, the proposed modified S5.388 and Resolution IMT (WRC-2000) identify the 698-960 MHz, 1 525-1 559 MHz, 1 610-1 660.5 MHz, 1 710-2 025 MHz, 2 110-2 200 MHz, 2 483.5-2 690 MHz bands for potential IMT-2000 use.[1]

Furthermore, the United States believes that it is essential not to tie specific technologies to specific frequency bands. In keeping with its technology-neutral belief that existing mobile operators should be free to evolve to IMT-2000 and beyond as the market demands, the United States has proposed several bands for the terrestrial and satellite components of IMT-2000 that are already allocated for mobile and mobile-satellite services. IMT-2000 and other advanced communication applications

[1] Regarding the frequency bands 1 525-1 559 MHz and 1 626.5-1 660.5 MHz, identified for the satellite component of IMT-2000, there are associated WRC-2000 issues in agenda item 1.10 and Resolution 218 that need to be resolved regarding AMS(R)S. If the satellite component of IMT-2000 uses these bands, account must be taken of the priority of AMS(R)S communications over all other communications as described in RR S5.357A and S5.362A.

will naturally evolve from existing technologies in response to market demand, allowing current operators and new licensees in existing mobile and mobile-satellite bands to bring advanced services to consumers as rapidly as new technology allows. This approach has the advantage of not artificially tying the rollout of new technology and service to new spectrum as administrations assess their ability to use that spectrum for IMT-2000 and other advanced communication applications. Although ITU plays an invaluable role in facilitating IMT-2000 and other advanced communication applications, it will be administrations, technology developers, equipment manufacturers and service providers that will ultimately decide when to introduce IMT-2000 and other advanced communication applications based on market factors. The United States believes that support for this evolutionary approach in existing mobile bands will likely lead to a more expeditious implementation of IMT-2000 and other advanced communication applications in bands that overlap globally.

The United States realizes that it may not be possible for many administrations to make available the large amount of contiguous, globally-harmonized spectrum for use by IMT-2000 and other advanced communication applications. The difficulty arises from the need of many administrations to consider the investment of existing licensees, the impact on consumers and other users of existing services and the flexibility to authorize other systems based on national needs. Many administrations are currently studying the identified bands to determine their availability for IMT-2000 and other advanced communication applications, the availability of comparable replacement spectrum to which current and emerging uses might migrate, and the costs of relocation as compared to the benefits of global harmonization of spectrum for IMT-2000 and other advanced communication applications. The proposal acknowledges the importance of these national studies, and calls for the adoption of Resolution YYY (WRC-2000) - resolving that administrations expeditiously complete their studies and update ITU-R regarding their findings. The results of these national studies and information on national decisions on selection of spectrum for IMT-2000 and other advanced communication applications will be useful for administrations wishing to implement such systems. Resolution YYY (WRC-2000) also invites ITU-R to conduct studies that address issues related to the use of the identified bands for IMT-2000 and other advanced communication applications, including band sharing, global roaming, and interference issues.

Spectrum

In accordance with the above principles, the United States believes the following bands should be identified for potential use by IMT-2000 and other advanced communication applications. The bands are broken out by terrestrial and satellite components.

Terrestrial

The United States proposes the following bands for the terrestrial component of IMT-2000 and other advanced communication applications: 698-960 MHz, 1 710-1 885 MHz, 2 500-2 690 MHz.[2] In addition, the bands 1 885-2 025 MHz and 2 110-2 200 MHz, which are already included in RR S5.388, should continue to be listed for use by IMT-2000 and other advanced communication applications. However, to eliminate any ambiguity in RR S5.388, the United States is proposing a

[2] Existing United States licensees operating in the 824-849 MHz, 869-894 MHz, 1 850-1 910 MHz and 1 930-1 990 MHz bands have expressed an interest in providing terrestrial IMT-2000 and other advanced communications applications. In addition, the Federal Communications Commission has received specific proposals to permit advanced communications applications to operate terrestrially in the 746-764 MHz, 776-794 MHz and 2 110-2 150 MHz bands.

modification that clarifies that administrations may continue to use spectrum identified for IMT-2000 and other advanced communication applications for other uses.

Section 1.1.1.1 of the CPM Report notes that it is desirable to meet the projected IMT-2000 spectrum requirements by identifying a limited number of contiguous global bands in order to reduce the cost, size and complexity of IMT-2000 terminal and network equipment and deployment, and provide the economies of scale for the mass market.

Satellite

The United States recognizes that their inherent global coverage of satellites makes them a key element of worldwide IMT-2000 and other advanced communication applications. As WRC-2000 considers the use of allocations for IMT-2000 and other advanced communication applications, it should identify sufficient global and regional spectrum for the satellite component. The CPM Report notes that “[a]vailability of global spectrum is particularly important for the satellite component.” (Section 1.1.2.1.) Further, the CPM Report advises that “[c]onsideration should be given to identifying existing MSS allocations between 1 and 3 GHz for satellite IMT-2000 applications. It is foreseen that most of the MSS bands between 1 and 3 GHz could be used for IMT-2000 in the longer term.” (Section 1.1.2.1.)

The United States supports the CPM Report statements and proposes to identify the following existing MSS allocations in bands between 1 and 3 GHz for the satellite component of IMT-2000 and other advanced communication applications: 1 525-1 559/1 626.5-1 660.5 MHz, 1 610-1 626.5/2 483.5-2 500 MHz, 1 980-2 010/2 170-2 200 MHz, 2 500-2 520/2 670-2 690 MHz, and 2010-2 025/2 160-2 170 MHz (Region 2 only). This proposal identifies existing allocations that should satisfy the projected MSS requirements through 2010, and avoids the extremely difficult task of allocating new worldwide spectrum for new technologies.

SUP USA/12/194

RESOLUTION 212 (Rev.WRC-97)

Implementation of International Mobile Telecommunications-2000 (IMT-2000)*

Reasons: Consequential to USA/12/191.

ADD USA/12/195

RESOLUTION IMT (WRC-2000)

Global advanced communication applications including International Mobile Telecommunications-2000 (IMT-2000)

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that IMT-2000 is the ITU vision of global mobile access and is scheduled to start service around the year 2000;

b) that IMT-2000 is an advanced communication applications concept intended to provide telecommunications services on a worldwide scale regardless of location, network or terminal used;

c) that inevitable changes in technology will lead to other advanced communication applications beyond IMT-2000;

d) that through integration of terrestrial mobile and mobile-satellite systems, different types of wireless access will be provided globally, including services available through the fixed telecommunication networks and those specific to mobile users;

e) that global roaming and the economies of scale of a global market are desirable and can be best achieved through the availability of worldwide spectrum for IMT-2000 and other advanced communication applications, in particular for the satellite component, because of their global/international nature and their diverse technical characteristics;

f) that when such alignment is not possible, multi-band phones and other new technologies may assist in achieving global roaming;

g) that technological advancement and market demand encourage the use of flexible regulatory approaches that will promote innovation and accelerate the delivery of advanced communication applications to consumers;

h) that ITU Recommendations accommodate the transition from earlier technologies to future technologies;

i) that for technical reasons, such as propagation factors and equipment design, the ITU-R has determined that consideration of additional spectrum requirements for the mobile users of IMT-2000 be focused on the frequency range below 3 GHz, however, the existing applications below 3 GHz were implemented in their current bands for similar technical reasons;

j) that ITU-R Report M.[IMT.SPEC] Spectrum Requirements for IMT-2000, forecasts a need for additional spectrum on a global basis for the terrestrial and satellite components in the year 2010;

k) that the radio specifications for IMT-2000, as well as their various technical characteristics, as presented in ITU-R Recommendations, support the evolution of first- and second-generation mobile systems to IMT-2000;

l) that there have been high levels of investment in existing systems that may not evolve to or be able to share with IMT-2000 systems. These systems may continue to operate in the bands or portions of the bands identified for IMT-2000 and other advanced communication applications, thereby reducing the amount of global spectrum potentially available to support those new applications;

m) that No. **S5.388** identifies bands for use by IMT 2000 systems,

noting

a) that administrations may implement IMT-2000 in any frequency band allocated to the mobile or mobile-satellite service;

b) that the identification of spectrum for IMT-2000 does not convey any status under the Radio Regulations of ITU but does provide uniform guidance to administrations, operators and manufacturers in terms of deploying IMT-2000 and other advanced communication applications;

c) that the implementation of the terrestrial component of IMT-2000 and other advanced communication applications, within the bands identified, is expected to commence in some bands as early as the year 2000, subject to market and technical considerations;

d) that the implementation of the satellite component of IMT-2000 and other advanced communication applications, in the bands identified and allocated to the MSS, could commence in some bands as early as the year 2000, subject to market and technical considerations;

e) that administrations who use all or parts of the frequency bands identified for IMT-2000 for first- and second-generation mobile systems may ultimately want to deploy IMT-2000 and other advanced communication applications in these bands;

f) that administrations who use the frequency bands identified for IMT-2000 for applications other than mobile systems as specified in *noting e)* may want to give the operators of these systems the flexibility to either continue to provide the current services or to evolve their systems to the provision of other terrestrial services such as IMT-2000;

g) that some administrations will be conducting studies prior to making decisions on their implementation of certain bands;

h) that, in accordance with Resolution **YYY (WRC-2000)**, studies will be conducted in many countries and in ITU-R regarding the possible implementation of IMT-2000 and other advanced communication applications in portions of the identified bands,

invites administrations

1 to adopt regulatory and spectrum decisions that protect the existing investment in mobile telecommunication systems and facilitate the ability for existing operators to evolve their systems towards IMT-2000 and beyond based on marketplace needs;

2 to adopt regulatory and spectrum decisions that ensure operators have the flexibility to provide the services and use the diverse technologies that best meet marketplace needs;

3 to give due consideration to protecting the investment in other existing radio services and to lessening the impact on existing users;

4 to adopt appropriate and reasonable mechanisms to address the cost of relocation and to ensure provision of comparable replacement spectrum in those cases where relocation is deemed necessary,

urges

that, administrations deploying IMT-2000 systems should use the relevant international technical characteristics, as identified by ITU-R and ITU-T Recommendations,

resolves

1 that administrations planning to implement terrestrial IMT-2000 and other advanced communication applications, consider the use of the bands or portions thereof: 698-960 MHz, 1 710-2 025 MHz, 2 110-2 200 MHz and 2 500-2 690 MHz (noting that the bands 2 500-2 520 MHz and 2 670-2 690 MHz are also identified for the satellite component);

2 that administrations planning to implement satellite IMT-2000 and other advanced communication applications, consider the use of the bands or portions thereof: 1 525-1 559/1 626.5-1 660.5 MHz, 1 610-1 626.5/2 483.5-2 500 MHz, 1 980-2 010/2 170-2 200 MHz, 2 500-2 520/2 670-2 690 MHz, and where appropriate within regional mobile satellite allocations consider the use of the bands or portion thereof: 2 520-2 535/2 655-2 670 MHz and 2 010-2 025/2 160-2 170 MHz (noting that the bands 2 500-2 690 MHz are also identified for the terrestrial component)[1].

Reasons: To support a flexible international allocation approach that preserves the prerogatives of administrations to implement IMT-2000 systems as appropriate. This proposal supports the evolution of existing cellular and PCS systems to IMT-2000, while at the same time identifying new spectrum for advanced communication applications.

[1] The 2 500-2 520 MHz and 2 670-2 690 MHz bands are also identified for use by the IMT-2000 terrestrial component. When considering such use prior to 1 January 2005 (see Nos. **S5.414** and **S5.419**), administrations should recognize that this may limit the use of these MSS allocations by the satellite component of IMT-2000.

ADD USA/12/196

RESOLUTION YYY (WRC-2000)

Issues for further study regarding the implementation of advanced communication applications such as International Mobile Telecommunications-2000 (IMT-2000) in the frequency bands identified in No. S5.388

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-2000 has updated the identification of frequency bands available for IMT-2000 and other advanced communication applications, as stated in the modification to No. **S5.388** and the new Resolution **IMT (WRC-2000)**;

b) that all or portions of the bands identified for IMT-2000 are currently used by second-generation mobile communication systems, systems of other radio services, or mobile-satellite systems;

c) that Recommendation ITU-R M.1036 is concerned with implementation considerations with respect to spectrum for IMT-2000 in the bands 1 885-2 025 MHz and 2 110-2 200 MHz;

d) that Recommendation ITU-R M.1308 is concerned with the evolution of existing mobile communication systems to IMT-2000;

e) that administrations may have differing additional IMT-2000 spectrum requirements and may wish to implement IMT-2000 in certain frequency bands and not others, or may wish to implement IMT-2000 at different times,

considering further

f) that IMT-2000 is an advanced communications concept intended to provide telecommunications services on a worldwide scale regardless of location, network or terminal used;

g) that various technical approaches may be available in the future to provide for global roaming across mobile radio systems that operate in different frequency bands;

h) that inevitable changes in technology will lead to other advanced communication applications beyond IMT-2000,

noting

a) that all or parts of the 1 850-1 910/1 930-1 990 MHz band are used by several Region 2 administrations for second-generation mobile communication systems and that the operators of these systems may wish to have these systems evolve to IMT-2000;

b) that all or parts of the 1 710-1 785/1 805-1 885 MHz are used by many Region 1 and 3 administrations for second-generation mobile communication systems and that the operators of such systems may want to use these bands for IMT-2000;

c) that administrations who use the 2 500-2 690 MHz band for fixed systems may want to give the operators of these systems the flexibility to either continue to provide fixed services or to evolve to the provision of IMT-2000 and other advanced communication applications;

d) that, due to the level of investment in current uses and difficulties in identifying spectrum alternatives, administrations will continue to study the 698-960 MHz, 1 710-1 885 MHz and 2 500-2 690 MHz bands or portions of those bands for IMT-2000 and other advanced communication applications in their countries,

resolves

that administrations expeditiously complete their national studies and update ITU-R regarding the results of their studies and their selection of spectrum for IMT-2000 and other advanced communication systems,

invites ITU-R

1 to study how first- and second-generation mobile communication system band plans can be used to accommodate evolution of first- and second-generation mobile communication systems to IMT-2000 and other advanced communication systems;

2 to study means to facilitate global roaming across different regional band plans within the bands identified for IMT-2000 and other advanced communication systems;

3 to study the sharing issues related to the deployment of IMT-2000 systems in portions of the bands identified for IMT-2000 and other advanced communication systems;

4 to maintain a database of national studies and decisions on selection of spectrum for IMT-2000 and other advanced communication systems.

Reasons: To recognize the need of many administrations to continue to study these bands for possible use for IMT-2000 and other advanced communication applications and provides a mechanism to report the results of those studies and national decisions to ITU-R.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 2 to Document 12-E
10 April 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROPOSALS RELATING TO PP-98 RESOLUTIONS

Plenipotentiary Resolution 86

Improving the satellite coordination and notification process

There is a growing backlog problem in processing coordination requests and notifications by the Radiocommunication Bureau (BR). The backlog in coordination requests is increasing, and even if it were not increasing, it would take BR three years to address the number of submissions now in backlog. Fundamental reform of the coordination process appears to be needed. Short-term, interim and long-term solutions need to be developed. It cannot be emphasized enough that, achieving such reforms for the short term, must be accomplished at WRC-2000, and that fundamental reforms, mid-term and long term, would also need to be developed for WRC-03 and perhaps later.

Significant reforms to the process requiring changes to the Radio Regulations (RR) are long-term solutions and would not address the current backlog in a sufficiently rapid manner. Extraordinary measures are needed to eliminate the backlog in processing and publishing satellite coordination requests. The large and growing backlog cannot be addressed by chiseling away at it.

A solution to the backlog needs to be agreed at WRC-2000 and implemented through a Resolution adopted by the Conference. The Resolution would be needed for immediate application. Such a Resolution is proposed by the United States to address the backlog with some extraordinary measures as summarized below. To the extent these measures are appropriate for the long term, this Conference and WRC-03 should modify the body of the Radio Regulations accordingly.

The Resolution retains the current coordination procedure between administrations but suspends certain actions of the Radiocommunication Bureau in regard to its role in the coordination procedures. Since coordination requests for geostationary networks constitute 95 per cent of the backlog, the Resolution addresses only filings for geostationary systems.

The proposed Resolution:

- **Mandates electronic filing for any new submissions** - Mandatory electronic filing should be linked to improved capture and validation software. This software should make checks against the prepared data the same as in BR examinations so as to eliminate common errors and linkage problems from one part of the submission to other parts. Operators and administrations would likely submit coordination requests in electronic form if the software and interfaces were more fully developed and more user friendly. One of the significant time-consuming parts of the process for BR is the data capture and the associated validation with the exchange of correspondence with administrations to clarify the data. Electronic submissions in this part of the process should be of great help in addressing the backlog.

- **Suspends the requirement for BR to identify administrations to whom each coordination request should be addressed** - BR would continue to perform a technical examination of the filed parameters, checking that the filing is in line with the Radio Regulations and that pfd, tolerance, e.i.r.p. levels, etc. are not exceeded, and then simply publish the request for coordination without identifying administrations to whom the coordination request should be addressed. The administrations would carry out a self-identification by means of Appendix S8 calculations or orbital separation trigger and advise the administration concerned, with a copy to BR, where coordination was required. BR would then publish, after the four-month comment period, the list of administrations that are included in the coordination of a specific network. This list would form the basis of the Bureau's examination for compliance with the coordination procedure when the network is notified. Suspending the identification of administrations by BR would considerably speed up the processing of a notification submission as well as the coordination request.
- **Permits the application of an orbital separation trigger for coordination** between GSO FSS networks that operate in the congested bands: 3 400-4 200/5 850-6 725 MHz, certain portions of the range 10.95-14.5 GHz, plus 17.7-20.2/27.5-30.0 GHz.
- **Provides for BR to make available pending coordination requests "as received" prior to validation and capture by BR** so that administrations could begin the coordination at an early stage. All coordination requests (new and pending, electronic or paper) should be made available "as filed" prior to processing and publication by BR. Electronic submissions and captured data would be available via the website. Since paper filings converted to graphical files could entail rather large-sized files making downloading from the ITU website cumbersome, BR would make available such graphical files by CD distributions. Distributing coordination requests on CD may be helpful as well to those entities that do not have access to an infrastructure capable of high-speed access to the Bureau's website.

The Resolution makes clear the time period involved and at what stage the provisions are to be applied; it defines the minimum examinations by BR; makes clear in all cases that pfd examinations for protection of terrestrial systems would be retained.

Measures applied to the backlog would be applied to new submissions as well.

Need to assist developing countries

Developing countries often rely on the "safety-net" in the current procedures which is provided by the Bureau under the provisions of No. S9.36, in which the Bureau identifies affected administrations that may need to be included in the coordination process. While simplifying the administrative workload of the Bureau by suspending this aspect of the Bureau's examinations, the proposed suspension of BR examinations would not obviate the "safety-net" provided to developing countries. Assistance provided by BR under No. S7.6 would be maintained.

ADD USA/12/157

DRAFT RESOLUTION RP (WRC-2000)

Temporary procedures for processing coordination requests for geostationary-satellite networks

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) Resolution 86 of the Plenipotentiary Conference (Minneapolis, 1998);

b) that there now exists a large backlog of satellite network coordination requests pending with the Radiocommunication Bureau such that elimination of this backlog at current processing rates and with no new filings could take the Bureau more than three years to accomplish;

c) that 95 per cent of this backlog consists of coordination requests for geostationary-satellite networks;

d) that WRC-97 established the period between receipt of the Advance Publication information and the placing of satellite networks into use as five years (Nos. **S9.1**, **S11.44**) and the extension period as two years (Nos. **S11.44B** to **S11.44I**),

recognizing

a) the obligation of administrations to respond to coordination requests occurs at the end of the comment period following publication (Nos. **S9.51** and **S9.52**);

b) in view of the processing delay, a satellite operator may have to wait three years to coordinate its network and, because of the five-year limit to place a network into operation, be faced with a reduced time window in which to accomplish coordination;

c) extraordinary measures are needed to enable the Bureau to eliminate the backlog in processing satellite network coordination requests;

d) that this Conference needs to take extraordinary measures to ensure the continued viability and credibility of the ITU satellite coordination process,

resolves

1 that the interim procedures set forth in the Annex to this Resolution shall be applied from the close of this Conference until a subsequent competent WRC abrogates or modifies the procedures herein;

2 that the procedures set forth in the Annex shall be applicable to all geostationary-satellite network coordination requests awaiting publication at the Bureau at the close of this Conference and to all coordination requests for geostationary networks received on or after 3 June 2000;

3 that only relevant provisions of the Radio Regulations cited in the Annex for suspension shall be temporarily suspended in favour of the procedures of the Annex,

instructs

the Bureau to keep the Council and Members periodically informed of the results of these measures on the backlog and report them to the next competent Conference.

DRAFT ANNEX 1 TO RESOLUTION RP (WRC-2000)

Temporary procedures for geostationary-satellite networks

1 Form of filing

Starting from 3 June 2000, all data for geostationary-satellite network coordination requests shall be filed in electronic format as described in Attachment 1 to Circular Letter CR/58. The preferable form for submitting graphical information is the graphics data format described in Attachment 2 to Circular Letter CR/58. Where the graphics data format is not feasible, administrations are encouraged to submit graphics in the Portable Document Format (PDF). Submission of graphics in paper form will, however, continue to be accepted.

2 Processing by the Bureau of coordination requests for geostationary networks

The Bureau:

a) shall examine the coordination request only for completeness and for conformity with the Table of Frequency Allocations and other provisions of the Radio Regulations (Nos. **S9.35** and **S11.31**) including examinations in respect to the hard limits of the Regulations for pfd and e.i.r.p.;

b) shall not identify administrations with which coordination may need to be effected between satellite networks using the geostationary-satellite orbit in any space radiocommunication service and between a satellite network using the geostationary-satellite orbit and satellite networks using non-geostationary orbits in any space radiocommunication service (the Bureau's calculation of coordination thresholds and identification of administrations under Nos. **S9.36**, **S9.37** and **S9.40** are suspended for the period described in *resolves* 1. The identification of non-geostationary satellite networks under No. **S9.13** and other geostationary-satellite networks under No. **S9.7** with which coordination is necessary shall continue to be the responsibility of the satellite administrations/operators. See paragraph 4 below. Those administrations with limited resources for this purpose may utilize the Bureau's assistance in accordance with No. **S7.6**);

c) shall continue to identify administrations having terrestrial service assignments with overlapping frequency bands for coordination of the frequency assignments of geostationary-satellite networks with those terrestrial services under Nos**. S9.11A** and **S9.21**.

3 Publication

a) The complete set of data for coordination requests shall be published for comment by the Bureau in its International Frequency Information Circulars in accordance with No. **S9.38**.

b) Coordination request data for geostationary-satellite networks received prior to 3 June 2000; and

i) captured in the Bureau's computer system but not yet published shall be made available online at the earliest possible time via the Bureau's website; while

ii) paper filings received and not yet captured by the Bureau shall be made available in image format via CD distribution within 60 days from the close of this Conference;

c) Coordination request data for satellite networks submitted in accordance with above paragraph 1, but not yet published, shall be made available online via the Bureau's website within 30 days of submission.

4 Role of administrations/operators

The role of the administrations and operators in the geostationary-satellite coordination process is basically unchanged during the period described in *resolves* 1. Administrations/operators will continue to identify the networks with which coordination is necessary in accordance with the relevant provisions of the Radio Regulations. It is these networks which are used as the basis for agreements specified in the notification of the coordinated frequency assignments for a satellite network.

In assessing the need for coordination for the fixed-satellite service in the frequency bands 3 400-4 200/5 850-6 725 MHz, certain portions of the range 10.95-14.5 GHz, plus 17.7-20.2/27.5-30.0 GHz, the need for coordination shall be based on a coordination arc trigger in accordance with the attachment to this Annex. The coordination arc trigger method is to be applied as of 3 June 2000 to all coordination requests for geostationary networks that are awaiting regulatory examination by the Bureau and to new filings utilizing these bands.

For other bands, Appendix **S8** thresholds would continue to be used in all other relevant instances of coordinating geostationary networks. Those administrations with limited resources for this purpose may utilize the Bureau's assistance in accordance with No. **S7.6**.

5 Bureau examinations under Article S11

When the Bureau conducts its examination of notifications of satellite networks, subject to the above temporary procedures, for compliance with the coordination provisions under No. **S11.32**, it shall base its findings only on the basis of the list of networks or administrations provided by the notifying administration and those administrations commenting on the publication of the coordination request. The comments and findings shall be in accordance with above paragraphs 2*b)* and 4.

ATTACHMENT

Coordination under the orbital arc trigger

The procedure in this attachment is applicable only for coordination between geostationary fixed-satellite service networks having frequency assignments utilizing the same direction of transmission in the bands 3 400-4 200/5 850-6 725 MHz, certain portions of the range 10.95-14.5 GHz, plus 17.7-20.2/27.5-30.0 GHz. The specific bands are set forth in the table below. In assessing the need for coordination, administrations and satellite operators shall make that determination based on the orbital separations in the table below.

Frequency range(s)	Orbital separation outside of which coordination is not required (degrees)
3 400-4 200 MHz 5 850-6 725 MHz	±10
10.95-11.2 GHz 11.45-11.7 GHz 11.7-12.2 GHz (Region 2) 12.5-12.75 GHz (Regions 1 and 3) 12.7-12.75 GHz (Region 2) 13.75-14.5 GHz	±9
17.7-20.2 GHz 27.5-30.0 GHz	±8

A geostationary-satellite network with overlapping frequency assignments and located outside the coordination arc of the table may be included in the coordination process where the administration responsible for that network can demonstrate that the increase in noise temperature due to the network being coordinated exceeds six per cent. The relevant Appendix **S4** data is necessary for this calculation.

A geostationary-satellite network with overlapping frequency assignments and located within the coordination arc of the table need not be included in the coordination process if either the coordinating administration or administration responsible for that network can demonstrate that the increase in noise temperature due to the network being coordinated is equal to or less than six per cent. A geostationary-satellite network that is the subject of such a demonstration would be considered a network for which coordination would need to be effected, until such time as the demonstration is agreed or confirmed between the concerned administrations. The relevant Appendix **S4** data is necessary for this calculation.

Reasons: This Resolution retains the current coordination procedure between administrations but suspends certain actions of the Radiocommunication Bureau in regard to its role in the coordination procedures. Since coordination requests for geostationary networks constitute 95 per cent of the backlog, the Resolution addresses only filings for geostationary systems.

The Annex outlines the temporary application procedures for geostationary-satellite networks.

The Attachment addresses specialized coordination procedures for geostationary fixed-satellite service networks under the "Orbital arc trigger".

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

ISTANBUL, 8 MAY – 2 JUNE 2000

Addendum 1 to Document 12-E
23 March 2000
Original: English

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

PROPOSALS RELATING TO PP-98 RESOLUTIONS

Resolution 88, Plenipotentiary Conference, (Minneapolis, 1998)

Proposal to add a new Section III to Article S9

Background information

In Resolution 88, the Plenipotentiary Conference, (Minneapolis, 1998), instructs WRC-2000 to consider whether any relevant amendments to the Radio Regulations with respect to satellite cost recovery procedures may be necessary. This matter has been discussed in several forums since consideration by the Plenipotentiary Conference. The ITU Council at its 1999 session was of the view, in Decision 482, that Resolution 88 (PP-98) implied that WRC-2000 may also consider any consequence of non-payment taking into account unforeseen circumstances and the principles contained in the Constitution and Convention relating to the sovereign right of Member States in gaining access to spectrum and orbit resources. The report to the Council of the Satellite Network Cost-Recovery Working Group mentioned that some considered that the consequences of non-payment should be that the delinquent network should not be taken into account.

As WRC-2000 will address this matter, regulatory changes are proposed to Article S9 to elaborate on a procedure addressing consequences of the non-payment of processing charges incurred under the satellite cost-recovery schedules.

In view of the importance to all administrations of processing a request for coordination, it is suggested that the procedure for addressing instances of non-payment of filing fees should be laid out clearly, in the same article of the Radio Regulations that establishes other requirements for filing for coordination and notification.

ARTICLE S9

Procedure for effecting coordination with or obtaining agreement of other administrations[1, 2, 3, 4, 5]

ADD USA/12/146

Section III – Procedure for collection of charges for processing publications and requests for coordination of space systems

ADD USA/12/147

S9.66 When the Radiocommunication Bureau assesses charges for the processing of publications and coordination requests for space systems in accordance with Resolution **88 (PP-98)**, ITU Council Decision 482 and subsequent relevant decisions of the Council, the provisions of this section shall apply.

ADD USA/12/148

S9.67 Within 30 days after publication of the relevant space system Special Section in its International Frequency Information Circular, the Radiocommunication Bureau shall transmit an invoiced billing to the entity responsible for paying charges under No. **S9.66**, either the notifying administration or operating entity as may be elected by the administration. The notifying administration shall be kept informed, in the latter case, at all stages of billing and payment. Upon transmitting the invoiced billing, the Radiocommunication Bureau will publish on an unrestricted basis on its website the satellite network name, entity invoiced, ITU Special Section number, billed amount, and the date the amount is due.

ADD USA/12/149

S9.68 The notifying administration or operating entity shall remit its payment to the Radiocommunication Bureau no later than six months from the date of the transmitted invoice of No. **S9.67**. This six-month payment period shall not be extended for any reason. Upon receipt of payment, the Radiocommunication Bureau will immediately transmit a receipt to the payer and update its website indicating that the cost-recovery amount for the satellite network has been paid. If payment is not received within four months from the date of the transmitted invoice, the Bureau shall send a reminder to the notifying administration or operating entity. The reminder shall include notice that non-receipt of payment within six months from the date of the original invoice will result in the relevant publication no longer being taken into account and the Special Sections being suppressed.

ADD USA/12/150

S9.69 If the Bureau has no record of receipt of payment within the six-month time period specified in No. **S9.68**, the Bureau shall consult with the notifying administration or operating entity to determine whether payment has been made. The notifying administration or operating entity, as appropriate, shall have 30 days to prove to the Bureau that payment has been made so as to be received by the Bureau within the six-month time period specified in No. **S9.68**.

ADD USA/12/151

S9.70 If the complete payment has not been received by the Bureau by the expiry date specified in No. **S9.68** and the provisions of No. **S9.69** have been satisfied, the published Special Sections for the advance publication, request for coordination, request for a modification to the Plans of Appendices **S30** and **S30A**, or request for the application of Section III of Article 6 of

Appendix **S30B**, as appropriate, shall be suppressed and no longer taken into account. The Bureau shall publish this information in the International Frequency Information Circular.

Reasons: To establish a regulatory basis for satellite cost recovery and to codify procedures for the collection of payments. With one free publication per administration per year provided in the schedule of Decision 482, there should be no cost-recovery financial barrier to any administration having access to spectrum and orbit resources.

ADD USA/12/152

DRAFT RESOLUTION CR-1 (WRC-2000)

Early implementation of cost-recovery provisions

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) Resolution **39** of the Plenipotentiary Conference (Kyoto, 1994) on strengthening the financial base of ITU;

b) Resolution **88** of the Plenipotentiary Conference (Minneapolis, 1998) on implementation of cost recovery for satellite network filings;

c) Council Decision 482 on implementation of cost recovery for satellite network filings;

d) that this Conference adopted procedures for collection of charges pursuant to the above Resolutions and Decision,

recognizing

the need for immediate application of these new provisions,

resolves

that the Radiocommunication Bureau shall begin applying the cost-recovery procedures of new Section III of Article **S9** from 3 June 2000.

INTERNATIONAL TELECOMMUNICATION UNION

WRC-2000 WORLD RADIOCOMMUNICATION CONFERENCE

Document 12-E
12 January 2000
Original: English

ISTANBUL, 8 MAY – 2 JUNE 2000

PLENARY MEETING

United States of America

PROPOSALS FOR THE WORK OF THE CONFERENCE

CONTENTS

Introduction

In this document the United States makes proposals under a number of WRC-2000 agenda topics. It is anticipated that the United States will submit at a later date some additional proposals including proposals for future conferences. The United States also supports many of the common proposals of the Inter-American Telecommunications Commission ("CITEL"). The United States will consider adoption of additional CITEL proposals as they are completed.

Summary of the United States proposals

Agenda item 1.2

The United States supports the CITEL proposal that modifies Appendix **S3**.

The United States submits a proposal for the modification of Recommendation **66 (Rev.WRC-97)**.

Agenda item 1.3

The United States submits two proposals for this agenda item:

– a proposal to modify Appendix **S7** and consequential modifications to Appendix **S5**;

– a proposal for the suppression of Resolution **60**.

Agenda item 1.4

The United States supports the CITEL proposal for confirmation of the fixed service allocation in the 31.8-33.4 GHz (Resolutions **126** and **726**).

The United States submits a proposal concerning high-density applications in the fixed service at 55.78-56.26 GHz.

Agenda item 1.6.2

The United States supports the CITEL proposal not to identify a global control channel for IMT-2000.

Agenda item 1.7

The United States supports the CITEL proposal for protecting operational, distress and safety communications in HF bands used by the aeronautical mobile (R) and maritime mobile services.

Agenda item 1.8

The United States submits a proposal for communications by earth stations on board vessels using frequencies allocated to the fixed-satellite service and used by existing space segment in the fixed-satellite service.

Agenda item 1.9

The United States supports the CITEL proposal for no allocation for the mobile-satellite service (space-to-Earth) in any portion of the 1 559-1 567 MHz under agenda item 1.9. We also support the suppression of Resolution **220**.

Agenda item 1.11

The United States submits a proposal for the Tables of Criteria applicable to MSS allocations for the non-GSO systems below 1 GHz.

Agenda item 1.12

The United States supports the CITEL proposal for the modification of footnote **S5.541A** and the suppression of Resolution **121**.

Agenda item 1.14

The United States supports the CITEL proposal for Resolution **123** (Implementing feeder links of non-geostationary satellite networks in the mobile-satellite service in the band 15.43-15.63 GHz (space-to-Earth)).

Agenda item 1.15.1

The United States submits two proposals for this agenda item:

– a proposal for additional radionavigation-satellite service (RNSS) signals near 1 GHz;

– a NOC proposal regarding additional radionavigation-satellite service (RNSS) signals near 5 GHz.

Agenda item 1.15.2

The United States submits a proposal for an allocation for space-to-space use for RNSS.

Agenda item 1.16

The United States submits a proposal to modify the allocations above 71 GHz.

Agenda item 1.17

The United States support the CITEL proposal for Earth exploration-satellite (passive) and the space research (passive) services in the band 18.6-18.8 GHz on a primary basis in Regions 1 and 3.

Agenda item 1.18

The United States supports the CITEL proposal for the modification of Appendix **S18** and Resolution **342**.

Agenda item 1.19*bis*

The United States submits a proposal, which reflects the view that there is no need to repeat the work and discussion of WRC-95 and WRC-97.

Agenda item 1.20

The United States submits a modification of Appendix **S30** for the relaxation in the pfd limits for Alaska.

Agenda item 2

The United States submits a proposal for the modification of Resolution **27** and Resolution **28**.

Agenda item 4

The United States submits a proposal for the suppression of Resolution **63**.

Plenipotentiary resolutions

The United States submits a NOC proposal for Resolution **87** (Minneapolis, 1998).

Proposals for agenda item 1.2

A proposal for the modification of Recommendation 66 (Rev.WRC-97)

Background information

Recommendation **66** is being modified to reflect the current status of this document. Work has been completed on space service spurious emissions, so we are proposing the suppression of *considering f), recommends* 1 and 2. We are proposing the suppression of *recommends* 9 because TG 1/5 has concluded that OOB emission limits are not appropriate at this time.

MOD USA/12/1

RECOMMENDATION 66 (Rev.WRC-~~97~~2000)

Reasons: Editorial.

Studies of the maximum permitted levels of unwanted emissions

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that Appendix **S3** specifies the maximum permitted levels of spurious emissions, in terms of the mean power level of any spurious component supplied by a transmitter to the antenna transmission line;

b) that the principal objective of Appendix **S3** is to specify the maximum permitted levels of spurious emissions that, while being achievable, provide protection against harmful interference;

c) that excessive levels of unwanted emissions may give rise to harmful interference;

d) that while out-of-band emissions can also give rise to harmful interference, the Radio Regulations do not provide general limits for these emissions;

e) that while Appendix **S3** applies generally to the mean power of a transmitter and its spurious emissions, it also takes account of a variety of emissions where interpretation of the term "mean power", and thus its measurement, would be difficult, particularly in the cases of digital modulation broadband systems, pulsed modulation and narrow-band high-power transmitters;

SUP USA/12/2

f)

Reasons: Work has been completed on space service spurious emissions.

MOD USA/12/3

~~g~~f) that unwanted emissions from transmitters operating in space stations may cause harmful interference, particularly emissions from wideband amplifiers which cannot be adjusted after launch;

~~h~~g) that unwanted emissions may cause harmful interference to safety services and radio astronomy and space services using passive sensors;

Reasons: Consequential numbering changes.

MOD USA/12/4

~~i~~h) that, for technical or operational reasons, more stringent spurious emission limits than the general limits in Appendix **S3** may be required to protect specific services, such as safety services and passive services in specific bands or situations;

Reasons: Edited to conform to the concept in the recommends that limits may be needed for specific situations.

MOD USA/12/5

~~j~~i) that broadband digital modulation may cause unwanted emissions at frequencies far from the carrier frequency,

Reasons: Consequential number change.

noting

a) that safety services and passive services have in many cases been allocated frequencies adjacent or close to those of services employing high-power transmitters;

b) that some administrations have adopted more stringent limits for spurious emissions than those specified in Appendix **S3**,

SUP USA/12/6

recommends that ITU-R

1

Reasons: Work has been completed on space service spurious emissions.

SUP USA/12/7

2

Reasons: Work has been completed on space service spurious emissions.

MOD USA/12/8

~~3~~1 continue the study of spurious emission levels in all frequency bands, emphasizing the study of those frequency bands, services and modulation techniques not presently covered by Appendix **S3**;

~~4~~2 study the question of unwanted emissions resulting from transmitters of all services and all modulation methods, and, on the basis of those studies, develop a Recommendation or Recommendations for maximum permitted levels of spurious emissions and out-of-band emissions;

~~5~~3 establish appropriate measurement techniques for unwanted emissions, where those techniques do not currently exist, including the determination of reference levels for wideband transmissions as well as the applicability of reference measurement bandwidths;

~~6~~4 study the reasonable boundary of spurious emissions and out-of-band emissions with a view to defining such a boundary in Article **S1**;

~~7~~5 study those frequency bands and instances where, for technical or operational reasons, more stringent spurious emission limits than the general limits in Appendix **S3** may be required to protect safety services and passive services such as radio astronomy, and the impact on all concerned services of implementing or not implementing such limits;

~~8~~6 study those frequency bands and instances where, for technical or operational reasons, out-of-band limits may be required to protect safety services and passive services such as radio astronomy, and the impact on all concerned services of implementing or not implementing such limits;

Reasons: Consequential numbering changes.

SUP USA/12/9

9

Reasons: Suppressed because TG 1/5 has concluded that OOB emission limits are not appropriate at this time.

MOD USA/12/10

~~10~~7 report the results of studies under *recommends that ITU-R* ~~6, 7 and 8~~4, 5 and 6 above to a competent world radiocommunication conference(s).

Reasons: Consequential numbering change.

Proposals for agenda item 1.3

"to consider the results of ITU-R studies in respect of Appendix **S7/28** on the method for the determination of the coordination area around an earth station in frequency bands shared among space services and terrestrial radiocommunication services, and to take the appropriate decision to revise this Appendix"

A proposal to modify Appendix S7 and consequential modifications to Appendix S5

Background information

Appendix **S7** provides the methods for determining the coordination area around earth stations. These methods have not been updated in the Radio Regulations since 1979. Since that time system characteristics have changed, new bands have been allocated to satellite services, and propagation tools have been improved.

Recommendation ITU-R **SM.XX** consolidates the text of Recommendations ITU-R **847** through **849**, uses updated system characteristics, extends the frequency range, and separates the propagation aspects from other probability aspects. Therefore, it serves as a useful basis for updating Appendix **S7**.

Recognizing that the frequency bands covered by the methods for determining coordination areas, the system technical characteristics, and the potential operating scenarios will change with the decisions at each WRC, the United States proposes incorporating Recommendation ITU-R **SM.XX** into the Radio Regulations by reference. Even if Appendix **S7** is updated based on Recommendation ITU-R **SM.XX**, it will probably be out-of-date at the close of WRC-2000 based on decisions made at the Conference. It will remain so for years to come unless the recommendation is referenced to facilitate future updates. If the incorporation-by-reference method is not used, future updates will require a specific agenda item to be agreed. Given that it has required twenty years to update the current appendix and noting the rapid evolution of satellite and terrestrial radio communications, another long delay in updating the text would not be acceptable.

This proposed modification to Appendix **S7** involves the suppression of the entire text of the Appendix and its replacement with the "incorporation-by-reference" text as shown below. Furthermore, it includes updated references in Appendix **S5**, Table **S5-1**, and Appendix **S5**, Annex 1, Tables 2, 3 and 4.

Proposal[1]

SUP USA/12/11

APPENDIX S7

Method for the determination of the coordination area around an earth station in frequency bands between 1 GHz and 40 GHz shared between space and terrestrial radiocommunication services

Reasons: All text in the current Appendix S7 should be suppressed.

[1] Only the portion of the tables being modified is shown in this proposal.

ADD USA/12/12

APPENDIX S7

Method for the determination of the coordination area around an earth station in frequency bands between 0.1 GHz and 105 GHz shared between space and terrestrial radiocommunication services

The method for determining the coordination area around an earth station between the frequency bands between 0.1 GHz and 105 GHz shared between space and terrestrial radiocommunications services is given in Annexes 1 and 2 of Recommendation ITU-R SM.XX.

Reasons: To update the method for determining coordination areas and to provide a responsive mechanism for future updates.

MOD USA/12/13

A proposal for the suppression of Resolution 60

Background information

A proposal for the suppression of Resolution **60** is being submitted because this Resolution is no longer needed.

SUP USA/12/17

RESOLUTION 60

Relating to information on the propagation of radio waves used in the determination of the coordination area

Reasons: WP 3M provided updated propagation material to TG 1/6. Resolution no longer required.

Proposals for agenda item 1.4

"to consider issues concerning allocations and regulatory aspects related to Resolutions **126 (WRC-97), 128 (WRC-97)**, **129 (WRC-97)**, **133 (WRC-97)**, **134 (WRC-97)** and **726 (WRC-97)**"

A proposal concerning high-density applications in the fixed service

Background information

WRC-97, in its realignment of the 50.2-71 GHz spectral region, placed a primary allocation to the fixed service in the frequency band 55.78-59 GHz. Footnote **S5.547** and Resolution **726 (WRC-97)** indicate that this band (among others) is available for high-density applications in the fixed service.

With respect to 55.78-59 GHz, Resolution **726 (WRC-97)** resolves that administrations should take into account that this band is available for high-density application in the fixed service, when considering allocations or other regulatory provisions in relation to this band and requests ITU-R:

– to undertake studies leading to the identification of system characteristics of high-density systems in the fixed service in 55.78-59 GHz; and

– to undertake, as a matter of urgency, studies of technical and operational criteria and of methods to facilitate sharing between high-density systems in the fixed service and other services in 55.78-59 GHz.

Based upon study results contained within Recommendation ITU-R SA.1279, sharing is feasible between the EESS passive and the HDFS provided that the parameters assumed in the Recommendation are not exceeded. Additionally, the current state of the art out put power of a HDFS system is limited to a maximum of approximately –31.5 dBW/MHz.

Section IV – Table of Frequency Allocations

MOD USA/12/18

MOD USA/12/19

56.26-56.9	EARTH EXPLORATION-SATELLITE (passive) FIXED ADD S5.547 INTER-SATELLITE S5.556A MOBILE S5.558 SPACE RESEARCH (passive) S5.547 S5.557	

ADD USA/12/20

S5.EESS Within the band 55.78-56.26 GHz, the maximum e.i.r.p. of the FS is limited to –28.5 dBW/MHz in order to protect stations in the EESS passive service.

Reasons: ITU-R studies have shown that, without limitations on the power of high-density applications in the fixed service in the band 55.78-56.26 GHz, unacceptable interference may occur to passive sensors on board earth exploration satellites.

MOD USA/12/21

RESOLUTION 726 (WRC-~~97~~2000)

Frequency bands above 30 GHz available for high-density applications in the fixed service

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that there is a dramatically increasing demand for high-density applications in the fixed service resulting from the deployment of new mobile networks and from the rapid worldwide deregulation in the provision of local broadband services, including multimedia;

b) that the frequency range from 30 GHz to about 50 GHz is the range preferred to satisfy initial requirements, as indicated in *considering a)*, while the bands above about 50 GHz are preferred for similar applications but which take technical advantage of high atmospheric absorption;

c) that the lower part of the spectrum above 30 GHz has advantages for the fixed service in areas where longer path lengths are necessary;

d) that the 38 GHz band is already heavily used by many administrations for high-density applications in the fixed service;

e) that the needs of other services to which the relevant frequency bands are already allocated must be taken into account;

f) that the band 37-37.5 GHz is being planned for use by the space research service (space-to-Earth) to provide moon-to-Earth and planetary communication links;

g) that the band 37-38 GHz is being planned for use by the space research service to provide space based very long baseline interferometry;

h) that the deployment of high-density applications in the fixed service in some bands potentially presents sharing difficulties with other primary services allocated to the same band, e.g. the fixed-satellite service;

i) that operations in the space services, such as in the fixed-satellite service, in those bands used by high-density applications in the fixed service may lead to sharing difficulties;

j) that there is a need for global harmonization of new and existing allocations of radio frequency bands to facilitate coordination between administrations and encourage development of competitive products, through economies of scale, and the worldwide introduction of new telecommunication services, including the provision of reliable global information infrastructure access at an affordable cost,

resolves

that administrations should take into account that the bands 31.8-33.4 GHz[*], 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz are available for high-density applications in the fixed service, when considering allocations or other regulatory provisions in relation to these bands~~,~~.

SUP USA/12/22

requests ITU-R

1

2

urges administrations

Reasons: Consequential to the completion of the studies.

[*] The date of provisional application of this allocation shall be in conformity with Resolution **126 (WRC-97)**.

Proposals for agenda item 1.8

"to consider regulatory and technical provisions to enable earth stations located on board vessels to operate in the fixed-satellite service (FSS) networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz, including their coordination with other services allocated in these bands"

A proposal for communications by earth stations on board vessels using frequencies allocated to the fixed-satellite service and used by existing space segment in the fixed-satellite service

Background information

This item concerns provision of communications by earth stations on board vessels (ESVs) using frequencies allocated to the fixed-satellite service and used by existing space segment in the fixed-satellite service. These stations operate in three distinct modes: at sea; while stationary in or near port; and in motion approaching or departing from port.

Operations at sea (beyond a certain distance for near-shore coordination) by ESVs in the fixed-satellite service do not present a potential for interference to stations in the fixed service operating in accordance with the 6 GHz FS allocation, and therefore need not be coordinated. Operations while these earth stations are stationary at predetermined points can be coordinated bilaterally with fixed service systems. Technical and regulatory issues concern the potential for interference between in-motion operations by these ESVs operating close to shore and stations in the fixed service both on and offshore.

The studies that have been conducted in ITU-R have illustrated that the values for the minimum distance are principally affected by the interference criteria required to protect the fixed service and the number of passages per unit time by vessels equipped with earth stations. Based on different values for these assumptions, the results of these preliminary studies yielded a range of values for the minimum distance from 100 km to 540 km. It should be noted that studies submitted to the CPM by some administrations suggested values for the minimum distance of 150 km to 370 km. However, there should be a single minimum distance value.

Reasons: To establish regulatory and technical provisions for operations of earth stations on board vessels in the fixed-satellite service.

ADD USA/12/26

RESOLUTION ZZZ (WRC-2000)

Provisions to enable earth stations located on board vessels to operate in fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that there is a demand for global wideband satellite communication services on vessels;

b) that the technology exists that would permit the use of fixed-satellite services (FSS) networks by earth stations on board vessels (ESVs) operating in the 3 700-4 200 and 5 925-6 425 MHz bands;

c) that ESVs have the potential to cause unacceptable interference to the fixed service (FS) systems in the band 5 925-6 425 MHz;

d) that FS systems have the potential to cause interference to ESVs in the 3 700-4 200 MHz band;

e) that ESVs operating in these bands require considerably less than the full bandwidth in this FSS allocation and only a portion of the visible geostationary arc;

f) that there are a limited number of geostationary FSS systems that have global coverage;

g) that in order to ensure the protection and future growth of the FS, the ESV must operate with certain technical and operational constraints;

h) that administrations may authorize radiocommunication stations on off-shore structures and platforms for which they are responsible;

i) that based on appropriate assumptions a minimum distance can be calculated beyond which the ESV will not have the potential to cause unacceptable interference to the fixed service in this band,

noting

a) that operation within the territorial sea is at the discretion of the administration with territorial authority, in which case the relevant procedures of that administration will apply;

b) that operation of earth stations on vessels from specified fixed points at locations outside the territorial sea but for which an administration has territorial jurisdiction is fully within the FSS,

resolves

1 that the administration that issues the radio licence for the use of ESVs in these bands (licensing administration) shall ensure that such stations do not cause unacceptable interference to stations in the fixed service;

2 that licensing administrations shall ensure that ESVs are capable of operating in compliance with the requirements of this Resolution;

3 that operators of ESVs shall comply with the conditions established by the licensing administration(s);

4 that ESVs shall not claim protection from fixed service station transmissions;

5 that any transmissions from ESVs within a distance 200 km off any given coast shall be based upon the prior agreement of that coastal administration;

6 that the ESV system shall include means of identification and automatic mechanisms to terminate transmissions whenever the station operates outside its pre-authorized geographic (see *resolves* 5) or operational limits;

7 that ESVs shall be equipped so as to enable the licensing administration under the provisions of Article **S18** to verify earth station performance and to accomplish the switch off of the ESV transmission immediately upon request by an administration whose services may be affected;

8 that when ESVs operating beyond the territorial sea but within 200 km of the coast of an administration fail to comply with the terms required by that administration pursuant to *resolves* 3 and 5, then that administration may:

– request the ESV to comply with such terms or cease operation immediately; or

– request the licensing administration to require such compliance or immediate cessation of the operation;

9 that any licensing authority that licenses ESVs shall agree to maintain at all times a point of contact, which shall be published in an ITU circular, that may be contacted by an affected administration seeking assistance pursuant to *resolves* 3 and 5 above.

Proposals for agenda item 1.11

"to consider constraints on existing allocations and to consider additional allocations on a worldwide basis for the non-geostationary (non-GSO) MSS below 1 GHz, taking account the results of ITU studies conducted in response to Resolutions **214 (Rev.WRC-97)** and **219 (WRC-97)**"

A proposal for the Tables of Criteria Applicable to MSS allocations for the non-GSO systems below 1 GHz

Background information

A number of studies have been carried out since MSS allocations for non-GSO satellite systems were first agreed at WARC-92. These have led to ITU-R recommendations which indicate the sharing techniques which are being used by those systems to share with each other and other co-primary services.

The table below (Non-GSO MSS sharing summary) from Recommendation ITU-R M.[YA] "Methods for achieving coordinated use of multiple non-GSO MSS systems below 1 GHz and sharing with other services in existing MSS allocations" summarizes the techniques and recommendations applied to existing MSS allocations. Many of these techniques are being employed in practice successfully.

Non-GSO MSS sharing summary

	Narrow-band	**Wideband**
Fixed and mobile (148-149.9 MHz) (455-456 MHz) and (459-460 MHz in Region 2) (454-455 MHz by footnotes)	Combination: – Dynamic channel avoidance (Rec. ITU-R M.1039) – Low duty cycle – Brief message duration – (Rec. ITU-R M.1185)	Combination: – Low output power density – Brief message duration – Low data rate – Filtering at satellite – Geographical separation
Fixed and mobile (137-138 MHz) (400.15-401 MHz)	Ground level pfd per RR S5.208	Ground level pfd per RR S5.208
Meteorological satellites (137-138 MHz)* (400.15-401 MHz)	Assignment separation	Combination: – Low pfd at ground level – Cross polarization discrimination – Adaptive filter at satellite
Space operations Space research (137-138 MHz)	Channel avoidance	Combination: – Low pfd – Cross polarization discrimination
Space research (400.15-401 MHz)	Channel avoidance	Combination: – Low pfd – Cross polarization discrimination
Meteorological aids (400.15-401 MHz)	Channel avoidance	Combination: – Low pfd – Cross polarization discrimination

The constraints on existing allocations are reflected in the footnotes to the allocations, and in the Annex 1 to Appendix **S5**. These have evolved to their present form since WARC-92, and now reflect a balance with regard to sharing criteria among the primary services concerned.

These constraints have served to provide a basis for implementing non-GSO MSS systems in these bands and at the same time provide protection to other space and terrestrial services. Therefore in respect to the constraints of the MSS in existing allocations below 1 GHz, no further modifications are needed.

ARTICLE S9

Procedure for effecting coordination with or obtaining agreement of other administrations[1, 2, 3, 4, 5]

Section II – Procedure for effecting coordination[8, 9]

Sub-Section IIA – Requirement and request for coordination

NOC USA/12/27

S9.11A *e)* for a station for which the requirement to coordinate is included in a footnote of the Table of Frequency Allocations referring to this provision:

Reasons: No modifications are required to the Tables of Criteria applicable to MSS allocations for the non-GSO systems below 1 GHz as found in No. S9.11A, or to the footnotes containing constraints which apply to the pertinent allocations.

APPENDIX S5

ANNEX 1

1 Coordination thresholds for sharing between MSS (space-to-Earth) and terrestrial services in the same frequency bands and between non-GSO MSS feeder links (space-to-Earth) and terrestrial services in the same frequency bands

1.1 Below 1 GHz*

NOC USA/12/28

1.1.1 In the bands 137-138 MHz and 400.15-401 MHz, coordination of a space station of the MSS (space-to-Earth) with respect to terrestrial services (except aeronautical mobile (OR) service networks operated by the administrations listed in Nos. **S5.204** and **S5.206** as of 1 November 1996) is required only if the pfd produced by this space station exceeds –125 dB (W/m^2/4 kHz) at the Earth's surface.

Reasons: No modifications are required to the Tables of Criteria applicable to MSS allocations for the non-GSO systems below 1 GHz as found in No. S9.11A, or to the footnotes containing constraints which apply to the pertinent allocations.

NOC USA/12/29

1.1.2 In the band 137-138 MHz, coordination of a space station of the MSS (space-to-Earth) with respect to the aeronautical mobile (OR) service is required only if the pfd produced by this space station at the Earth's surface exceeds:

– –125 dB (W/m^2/4 kHz) for networks for which complete Appendix **3** coordination information has been received by the Bureau prior to 1 November 1996;

– –140 dB (W/m^2/4 kHz) for networks for which complete Appendix **S4**/**3** coordination information has been received by the Bureau after 1 November 1996 for the administrations referred to in § 1.1.1 above.

Reasons: No modifications are required to the Tables of Criteria applicable to MSS allocations for the non-GSO systems below 1 GHz as found in No. S9.11A, or to the footnotes containing constraints which apply to the pertinent allocations.

NOC USA/12/30

1.1.3 In the band 137-138 MHz, coordination is also required for a space station on a replacement satellite of a MSS network for which complete Appendix **3** coordination information has been received by the Bureau prior to 1 November 1996 and the pfd exceeds −125 dB(W/m^2/4 kHz) at the Earth's surface for the administrations referred to in § 1.1.1 above.

Reasons: No modifications are required to the Tables of Criteria applicable to MSS allocations for the non-GSO systems below 1 GHz as found in No. S9.11A, or to the footnotes containing constraints which apply to the pertinent allocations.

3.2 General considerations

NOC USA/12/31

TABLE 1

Earth stations operating at frequencies below 1 GHz

Reasons: No modifications are required to the Tables of Criteria applicable to MSS allocations for use by non-GSO systems below 1 GHz, as found in No. S9.11A, or to the footnotes containing constraints which apply to the pertinent allocations.

Proposals for agenda item 1.15.1

"to consider new allocations to the radionavigation-satellite service in the range from 1 to 6 GHz required to support developments"

A proposal for additional radionavigation-satellite service (RNSS) signals near 1 GHz

Background information

Additional radionavigation-satellite service (RNSS) signals will greatly enhance the accuracy, reliability and robustness of the civil global positioning system (GPS) by enabling more effective corrections to be made for the time delay effects of the ionosphere on the signals from space. The International Civil Aviation Organization (ICAO) has stated the requirement for an additional civil signal on GPS to support global navigation satellite system (GNSS) requirements and for space-based augmentation systems. A requirement for aeronautical users is having the protected signal operate within radio spectrum allocated to the aeronautical radionavigation service (ARNS), which would also include the possibility of terrestrial augmentation systems.

The United States has identified a third signal at 1 176.45 MHz to support GNSS developments. The third signal is proposed to be an international civil aviation safety-of-life service signal with a required bandwidth 24 MHz. Technical studies show compatibility between existing operational ARNS systems and the proposed new signal at 1 176.45 MHz. The power levels and signal structure will allow the operation of a relatively large number of co-frequency satellite and terrestrial stations to be in view of an RNSS receiver.

Section IV – Table of Frequency Allocations

MOD USA/12/32

890-1 350 MHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
960-1 215	AERONAUTICAL RADIONAVIGATION MOD S5.328	

S5.328 The band 960-1 215 MHz is reserved on a worldwide basis for the use and development of airborne electronic aids to air navigation and any directly associated ground-based and satellite-borne facilities. In the 1 164-1 188 MHz portion of this band, the radionavigation-satellite service (space-to-Earth) is also allocated worldwide on a primary basis. In this band stations of the radionavigation-satellite services, but not in the aeronautical radionavigation-satellite service, shall not cause harmful interference to, or claim protection from, stations of the aeronautical radionavigation and aeronautical radionavigation-satellite services.

Reasons: Additional radionavigation-satellite service (RNSS) signals will greatly enhance the accuracy, reliability and robustness of the civil global navigation satellite system (GNSS) by enabling more effective corrections to be made for the time delay effects of the ionosphere on the signals from space.

NOC proposal regarding additional radionavigation-satellite service (RNSS) signals

Background information

The 5 GHz band presents no unique advantages for new RNSS systems and all RNSS requirements can be satisfied by existing and new allocation to be implemented in the 1 200 and 1 600 MHz bands. The increased power required at 5 GHz compared to the lower frequencies makes an allocation for RNSS at 5 GHz questionable because it may not be feasible to implement satellite networks from an economic standpoint.

ITU-R studies to date do not support the need for an allocation for RNSS at 5 GHz. There are a number of unresolved sharing situations at 5 GHz including protection the international microwave landing system (MLS) and mobile-satellite (MS) feeder links now operating at 5 000-5 150 MHz.

There are recognized difficulties in fully protecting existing radio astronomy operations. See the CPM Report, section 2.4.1.3.1: "The separation distance between RNSS (space-to-earth) and the radio astronomy service would be a minimum of 10 MHz to protect radio astronomy inside its allocation. This may cause difficulties due to the radio astronomy receiver sensitivity outside the band allocated to the radio astronomy service."

Studies under Resolution **114 (WRC-95)** are continuing and could result in changes in the future use of the 5 000-5 150 MHz band.

NOC USA/12/33

4 800-5 830 MHz

Region 1	**Region 2**	**Region 3**
5 000-5 150	AERONAUTICAL RADIONAVIGATION S5.367 S5.444 S5.444A	

Reasons: ITU-R studies to date do not support the need for an allocation for RNSS at 5 GHz.

Proposals for agenda item 1.15.2

"to consider the addition of the space-to-space direction to the radionavigation-satellite service allocations in the bands 1 215-1 260 and 1 559-1610 MHz"

A proposal for an allocation for space-to-space use for RNSS to ensure the protection of space-based RNSS receivers

Background information

Radionavigation-Satellite Service (RNSS) systems such as the Global Positioning System and Global Navigation Satellite System are primarily being used in the space-to-Earth direction to provide service to terrestrial users. These systems are, however, also increasingly being used in the space-to-space direction by spaceborne users for such applications as spacecraft three-dimensional positioning and velocity determination; three-axis attitude control; precise time synchronization; precision orbit determination, and atmospheric science. The use of RNSS signals is presently protected only through a space-to-Earth allocation in the 1 215-1 260 and 1 559-1 610 MHz bands. Recognizing current and future operational usage of spaceborne RNSS receivers for scientific and commercial applications, it is important to add the space-to-space direction to the existing RNSS allocations so that these uses can be taken into consideration when changes to the use of these bands are contemplated.

Interference studies have been conducted to assess the sensitivity of spaceborne RNSS receivers to interference from radiolocation, Earth exploration-satellite (active), space research (active), fixed, mobile and aeronautical radionavigation services in the 1 215-1 260 MHz band; from the aeronautical radionavigation and fixed services in the 1 559-1 610 MHz band; and also their sensitivity to intra-service interference between radionavigation-satellite service systems in these two bands.

The ITU-R has concluded that the addition of a space-to-space direction to the 1 215-1 260 MHz and 1 559-1 610 MHz RNSS bands will not cause any additional interference to other services since it involves no change to the space-to-Earth transmissions.

Studies demonstrate that RNSS spaceborne receivers can operate satisfactorily in the presence of interference caused by systems in other services as well as other RNSS systems. Potential interference from services in adjacent bands was also examined.

Existing coordination procedures are adequate for space-to-space operations.

Reasons: Provide an allocation for space-to-space use for RNSS, which will ensure the protection of space-based RNSS receivers.

Proposals for agenda item 1.16

"to consider allocations of frequency bands above 71 GHz to the Earth-exploration satellite (passive) and radio astronomy services, taking into account Resolution **723 (WRC-97)**"

A proposal to modify the allocations above 71 GHz

Background information

The following proposals modify many of the Table of Frequency Allocations above 71 GHz to accommodate the requirements of the radio astronomy and Earth-exploration satellite (passive) services, while giving consideration to the needs of other services. The modifications to the Table of Frequency Allocations maintain the aggregate amount of spectrum allocated to the displaced services (including the fixed-satellite service), provide frequency blocks 5-9 GHz wide to accommodate future wideband multimedia systems while taking into account differences in atmospheric attenuation, and provide appropriate separation between services.

Resolutions XXX and YYY address the need for future study between co-allocated active services and between active and passive services at such a time when the technical characteristics of the active services become known. Also, the United States may submit at a later date a corrigendum to this proposal addressing allocations to active services within the bands 71-86 GHz.

MOD USA/12/37

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
71-74	FIXED FIXED-SATELLITE ~~(Earth-to-space)~~(space-to-Earth) MOBILE MOBILE-SATELLITE ~~(Earth-to-space)~~(space-to-Earth) ~~S5.149 S5.556~~	

Reasons: MSS and FSS uplinks and downlinks in 71-74 GHz and 81-84 GHz bands have been interchanged to avoid satellite downlinks in bands needed by RAS. Atmospheric absorption is only slightly higher in 71-74 GHz band than in 81-84 GHz band. The RAS footnotes S5.149 and S5.556 have been deleted in favour of allocations above 76 GHz. The reference to the 72.77-72.91 GHz band in footnotes S5.149 and S5.556 has been deleted.

MOD USA/12/38

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
74-75.5	BROADCASTING-SATELLITE FIXED FIXED-SATELLITE ~~(Earth-to-space)~~(space-to-Earth) MOBILE Space research (space-to-Earth) MOD S5.561	

MOD USA/12/39

75.5-76	~~AMATEUR~~ ~~AMATEUR-SATELLITE~~ BROADCASTING-SATELLITE FIXED FIXED-SATELLITE (space-to-Earth) MOBILE Space research (space-to-Earth) MOD S5.561 ADD S5.EEE

Reasons: BSS, which is currently allocated to the 84-86 GHz band, has been relocated to this band to protect RAS above 76 GHz. Atmospheric absorption is only slightly higher in 74-76 GHz band than in 84-86 GHz band. Amateur and amateur-satellite allocations have been shifted to 80.5-81 GHz. The new footnote S5.EEE protects existing amateur and amateur-satellite operations in the 75.5-76 GHz band until the year 200[X]. The FSS (Earth-to-space) allocation has been moved to 84-86 GHz band. The proposed allocations in the 74-84 GHz range preserve a contiguous 10 GHz space research downlink (secondary), which is required for space VLBI purposes. The footnote S5.561 has been modified to recognize the change in BSS allocation.

MOD USA/12/40

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
76-~~81~~77.5	RADIO ASTRONOMY RADIOLOCATION Amateur Amateur-satellite Space research (space-to-Earth) ~~S5.560~~MOD S5.149	

MOD USA/12/41

MOD USA/12/42

78-81	RADIO ASTRONOMY RADIOLOCATION Amateur Amateur-satellite Space research (space-to-Earth) ~~S5.560~~MOD S5.149

Reasons: The existing 76-81 GHz band has been divided into three sub-bands. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide in both the 76-77.5 GHz and 78-81 GHz bands. Radio astronomy is added as a secondary allocation in the 77.5-78 GHz band. Amateur and amateur-satellite services are shifted by 0.5 GHz, to accommodate BS, FSS and MSS downlinks at the lower portion of atmospheric window, and to avoid sharing with vehicular radars, which some administrations have authorized to operate in the 76-77 GHz band. There is no change in sharing between services, except for introduction of RAS allocation in the upper and lower sub-bands. These bands have been added to those listed under S5.149. The footnote S5.560 is deleted from the 76-77.5 and 77-78 GHz sub-bands, where it does not apply.

MOD USA/12/43

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**

Allocation to services		
Region 1	**Region 2**	**Region 3**
134-~~142~~136	AMATEUR AMATEUR-SATELLITE ~~MOBILE S5.553~~ ~~MOBILE-SATELLITE~~ ~~RADIONAVIGATION~~ ~~RADIONAVIGATION-SATELLITE~~ Radio astronomy ~~Radiolocation~~ ~~S5.149 S5.340 S5.554 S5.555~~	

Reasons: The amateur and amateur-satellite services are moved here from the 142-144 GHz band to avoid interference to radio astronomy at higher frequencies. Radio astronomy is added as secondary service. All footnotes are deleted, as they no longer apply to this band.

MOD USA/12/64

119.98-158 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
136-141	~~MOBILE S5.553~~ ~~MOBILE-SATELLITE~~ RADIO ASTRONOMY RADIOLOCATION ~~RADIONAVIGATION~~ ~~RADIONAVIGATION-SATELLITE~~ Amateur Amateur-satellite ~~Radiolocation~~ MOD S5.149 ~~S5.340 S5.554 S5.555~~	

Reasons: Services currently allocated to the 144-149 GHz band are moved to this band to facilitate realignment. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide. This band added to those listed under S5.149. Since this band is no longer passive, it is removed from S5.340. Footnote S5.554 no longer applies to this band and is deleted. Footnote S5.555 is no longer needed, as the radio astronomy service is allocated on a primary basis in the entire 136-141 GHz band.

MOD USA/12/65

119.98-158 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
141-142	FIXED MOBILE ~~S5.553~~ ~~MOBILE-SATELLITE~~ RADIO ASTRONOMY RADIOLOCATION ~~RADIONAVIGATION~~ ~~RADIONAVIGATION-SATELLITE~~ ~~Radiolocation~~ MOD S5.149 ~~S5.340 S5.554 S5.555~~	

MOD USA/12/66

MOD USA/12/67

144-~~149~~148.5	FIXED MOBILE RADIO ASTRONOMY RADIOLOCATION ~~Amateur~~ ~~Amateur-satellite~~ MOD S5.149 ~~S5.555~~	

Reasons: Allocations are transferred to the 141-148.5 GHz band from the 126-134 GHz band to allow for radio astronomy allocations in this band. The bandwidth has been reduced to 7.5 GHz to accommodate EES (passive) and SR (passive) requirements in the 148.5-151.5 GHz band. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide. Since the 141-142 GHz sub-band is no longer passive, S5.340 is deleted from that band and modified accordingly. All sub-bands are added to those listed under S5.149. Footnotes S5.554 and S5.555 no longer apply to any portion of this band and are deleted and modified accordingly.

MOD USA/12/68

MOD USA/12/71

151-~~156~~151.5	~~FIXED~~ ~~FIXED-SATELLITE (space-to-Earth)~~ ~~MOBILE~~ EARTH EXPLORATION-SATELLITE (passive) RADIO ASTRONOMY SPACE RESEARCH (passive) MOD S5.340

Reasons: The current passive allocation of 150-151 GHz has insufficient bandwidth for remote sensing observations and is not adequately protected from potential interference. The scientific requirement is for a 3 GHz band centred at 150 GHz for use in conjunction with water vapour observations around 183 GHz. Also, the 150.74 GHz nitrous oxide line at required for microwave limb sounding applications. All active services are relocated from this band to meet these requirements. Since the 148.5-151.5 GHz band is now purely passive, it is added to those listed under S5.340. For the same reason, there is no need to include the band 150-151 GHz in S5.149, and it is deleted from this footnote. Footnotes S5.385 (150-151 GHz band) and S5.555 (148.5-149 GHz band) are no longer needed and are deleted from these bands.

MOD USA/12/72

119.98-158 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
151.5-155.5	FIXED ~~FIXED-SATELLITE (space-to-Earth)~~ MOBILE RADIO ASTRONOMY RADIOLOCATION MOD S5.149	

Reasons: The FSS downlink allocation is incompatible with radio astronomy requirements in this band and is relocated elsewhere. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide. This band is added to those listed under footnote S5.149. The additional radiolocation allocation compensates for removal from the 126-134 GHz band.

MOD USA/12/73

119.98-158 GHz

Allocation to services

Reasons: The scientific requirement is for a 3 GHz band centred at 157 GHz for use in conjunction with water vapour observations around 183 GHz. This allocation is only required until 2018 since current planned and operational instruments are already in this band. By 2018, all of these applications will have transitioned to the 148.5-151.5 GHz band. The FSS downlink allocation is incompatible with radio astronomy requirements and is relocated. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide. These sub-bands are added to those listed under S5.149. EES operations in the band 155.5-158.5 GHz need to be protected until 01/01/2018. After this date the fixed and mobile services need to coordinate with radio astronomy sites only. The space research (passive) allocation is limited to space-based radio astronomy in this band.

MOD USA/12/76

158-202 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
158.5-164	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE MOBILE-SATELLITE (space-to-Earth)	

Reasons: Mobile-satellite allocation has been added to partially compensate for loss of 134-142 GHz band.

MOD USA/12/77

Allocation to services		
Region 1	**Region 2**	**Region 3**
164-~~168~~167	EARTH EXPLORATION-SATELLITE (passive) RADIO ASTRONOMY SPACE RESEARCH (passive) MOD S5.340	

Reasons: Passive sensors require only this 3 GHz band from the current 164-168 GHz passive allocation. It is essential to maintain the 164-167 GHz portion of the band passive. The MOD refers to the band limits and addition of the band to footnote S5.340 only, no change (NOC) is proposed to the allocations within this sub-band. This band, along with the band 148.5-151.5 GHz will become the harmonized reference window for passive sensor observations of the 183.31 GHz water vapour line. The band is also used for microwave limb sounding of the 164.38 GHz ClO line. This passive band has been added to those listed under S5.340; the 164-168 GHz band had been omitted from S5.340.

MOD USA/12/78

158-202 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**

174.5-~~176.5~~174.8	~~EARTH EXPLORATION-SATELLITE (passive)~~ FIXED INTER-SATELLITE MOBILE MOD S5.558 ~~SPACE RESEARCH (passive)~~ ~~S5.149 S5.385~~	

Reasons: Passive services do not need the 167-168 GHz band and this band is yielded to displaced active services. Fixed, mobile and inter-satellite services are added to the 167-174.8 GHz band as well as fixed-satellite downlinks to the 167-174.5 GHz band to compensate for deletions in other bands. Passive sensor allocations are deleted from the 174.5-174.8 GHz band to properly adjust the band edge for the 183.3 GHz remote sensing requirement. Footnotes S5.149 and S5.385 are deleted from these bands and are appropriately modified. Footnote S5.558 is added next to mobile allocations in this band and the footnote is modified to include the 167-174.8 GHz band due to sharing with the inter-satellite service.

MOD USA/12/82

158-202 GHz

Allocation to services

Reasons: The band 174.8-191.8 GHz is of crucial importance for passive sensing of the water vapour absorption line whose peak is at 183.31 GHz. Sharing with fixed and mobile services is not practical, so these services are relocated. The inter-satellite service needs to be limited to links between GSO satellites and to a pfd limit as specified in sharing studies. Footnote S5.YYY is added to reflect this requirement. The entire band is deleted from those listed under S5.149, S5.385 (secondary radio astronomy allocation). All applicable footnotes are appropriately modified. Since no terrestrial radio astronomy use of the band 182-185 GHz is possible due to high atmospheric absorption, the radio astronomy allocation is deleted. Active services are moved from the

190-191.8 GHz band to make room for the addition of passive sensor allocations. Footnote S5.554 is deleted from this band to reflect removal of active services, and modified to reflect this change. S5.341 does not apply to this band and is deleted. Footnote S5.340 has been modified to include this band.

MOD USA/12/87

231-~~235~~231.5	EARTH EXPLORATION-SATELLITE (passive) ~~FIXED~~ ~~FIXED-SATELLITE (space-to-Earth)~~ ~~MOBILE~~ RADIO ASTRONOMY SPACE RESEARCH (passive) ~~Radiolocation~~ MOD S5.340

Reasons: It is essential to maintain the 226-231.5 GHz band passive. The MOD refers to the band limits only; no change (NOC) is proposed to the allocations within this sub-band. Passive sensors require exclusive use of only the 226-231.5 GHz portion of the 217-231 GHz band for microwave limb sounding of atmospheric constituents. In addition, this band contains a 4 GHz reference window for higher frequency water vapour measurements. This band is of vital importance to the radio astronomy service for observations of the 230.5 GHz CO line. Footnote S5.340 is modified to take into account that 217-226 GHz band is no longer passive, while adding the 231-231.5 GHz band. The fixed and mobile services, as well as the fixed-satellite downlinks, have been deleted from the 231-231.5 GHz portion to allow passive observations in this band.

MOD USA/12/94

202-~~400~~1 000 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
231.5-235	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE Radiolocation	

Reasons: The only required change in this band is the 500 MHz upward adjustment of the lower band edge (see the previous modification).

MOD USA/12/95

202-~~400~~1 000 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
235-238	EARTH EXPLORATION-SATELLITE (passive) FIXED ~~FIXED-SATELLITE (space-to-Earth)~~ MOBILE RADIO ASTRONOMY SPACE RESEARCH (passive)	

Reasons: Passive sensors are limited to microwave limb sounding in the band 235-238 GHz and can share with terrestrial services due to the absorption characteristics of this band. The fixed-satellite downlink is not compatible with the radio astronomy requirement for this band and is reallocated elsewhere. The addition of a radio astronomy allocation and RES RAS satisfies the requirements for radio astronomy spectral line and wideband continuum observations from remote locations worldwide.

MOD USA/12/96

NOC USA/12/105

S5.341 In the bands 1 400-1 727 MHz, 101-120 GHz and 197-220 GHz, passive research is being conducted by some countries in a programme for the search for intentional emissions of extraterrestrial origin.

Reasons: This informational footnote is still accurate.

MOD USA/12/106

S5.385 *Additional allocation:* the bands 1 718.8-1 722.2 MHz~~, 150-151 GHz, 174.42-175.02 GHz, 177-177.4 GHz, 178.2-178.6 GHz, 181-181.46 GHz, 186.2-186.6 GHz and 257.5-258 GHz are~~ is also allocated to the radio astronomy service on a secondary basis for spectral line observations.

Reasons: The changes to this footnote are consequential to the changes made to the related allocations.

MOD USA/12/107

S5.553 In the bands 43.5-47 GHz, 66-71 GHz, 95-100 GHz, ~~134-142 GHz, 190~~191.8-200 GHz and 252-265 GHz, stations in the fixed and land mobile service may be operated subject to not causing harmful interference to the space radiocommunication services to which these bands are allocated (see No. **S5.43**).

Reasons: The changes to this footnote are consequential to the changes made to the related allocations.

MOD USA/12/108

S5.554 In the bands 43.5-47 GHz, 66-71 GHz, 95-100 GHz, ~~134-142~~126-134 GHz, 190-200 GHz and 252-265 GHz, satellite links connecting land stations at specified fixed points are also authorized when used in conjunction with the mobile-satellite service or the radionavigation-satellite service.

Reasons: The changes to this footnote are consequential to the changes made to the related allocations.

MOD USA/12/109

S5.555 *Additional allocation:* the bands 48.94-49.04 GHz~~, 97.88-98.08 GHz, 140.69-140.98 GHz, 144.68-144.98 GHz, 145.45-145.75 GHz, 146.82-147.12 GHz, 250-251 GHz and 262.24-262.76 GHz are~~ is also allocated to the radio astronomy service on a primary basis.

Reasons: The changes to this footnote are consequential to the changes made to the related allocations.

MOD USA/12/110

S5.556 In the bands 51.4-54.25 GHz, 58.2-59 GHz~~,~~ and 64-65 GHz~~, 72.77-72.91 GHz and 93.07-93.27 GHz~~, radio astronomy observations may be carried out under national arrangements.

Reasons: The changes to this footnote are consequential to the changes made to the related allocations.

MOD USA/12/111

S5.558 In the bands 55.78-58.2 GHz, 59-64 GHz, 66-71 GHz, ~~116-134~~122.5-126 GHz, ~~170-182~~167-174.8 GHz and 185-190 GHz, stations in the aeronautical mobile service may be operated subject to not causing harmful interference to the inter-satellite service (see No. **S5.43**).

Reasons: The changes to this footnote are consequential to the changes made to the related allocation.

MOD USA/12/112

S5.559 In the band~~s~~ 59-64 GHz~~ and 126-134 GHz~~, airborne radars in the radiolocation service may be operated subject to not causing harmful interference to the inter-satellite service (see No. **S5.43**).

Reasons: The changes to this footnote are consequential to the changes made to the related allocation. The radiolocation and inter-satellite services are no longer co-allocated in this spectral region.

NOC USA/12/113

S5.560 In the band 78-79 GHz radars located on space stations may be operated on a primary basis in the Earth exploration-satellite service and in the space research service.

Reasons: No change is required to this footnote.

MOD USA/12/114

S5.561 In the band ~~84-86~~74-76 GHz, stations in the fixed~~,~~ and mobile~~ and broadcasting~~ services shall not cause harmful interference to broadcasting-satellite stations operating in accordance with the decisions of the appropriate frequency assignment planning conference for the broadcasting-satellite service.

Reasons: The broadcasting-satellite allocation has been transferred to the 74-76 GHz band and the broadcasting and broadcasting-satellite services are no longer co-allocated.

NOC USA/12/115

S5.562 The use of the band 94-94.1 GHz by the Earth exploration-satellite (active) and space research (active) services is limited to spaceborne cloud radars.

Reasons: This footnote was the result of allocation decisions made at WRC-97 and no change is needed.

SUP USA/12/116

S5.564

Reasons: The radio astronomy allocation is now worldwide in the 261-265 GHz band, therefore a country footnote is no longer needed.

MOD USA/12/117

S5.565 The frequency band 275-~~400~~1 000 GHz may be used by administrations for experimentation with, and development of, various active and passive services. In this band a need has been identified for the following spectral line measurements for passive services:

– radio astronomy service:~~ 278-280 GHz and 343-348 GHz~~275-323 GHz, 327-371 GHz, 388-434 GHz, 426-442 GHz, 453-510 GHz, 623-711 GHz and 795-909 GHz;

– Earth exploration-satellite service (passive) and space research service (passive): 275-277 GHz, ~~300~~294-30~~2~~6 GHz, ~~324~~316~~-326~~324 GHz, 34~~5~~2-34~~7~~9 GHz, 363-365 GHz~~, and~~ 37~~9~~1-38~~1~~9 GHz, 416-434 GHz, 442-444 GHz, 496-506 GHz, 546-568 GHz, 624-629 GHz, 634-654 GHz, 659-661 GHz, 684-692 GHz, 730-732 GHz, 851-853 GHz and 951-956 GHz.

Future research in this largely unexplored spectral region may yield additional spectral lines and continuum bands of interest to the passive services. Administrations are urged to take all practicable steps to protect these passive services from harmful interference until the next competent world radiocommunication conference.

Reasons: These additional bands have been identified by various administrations as bands that will also be used for radio astronomy observations and spaceborne passive remote sensing.

ADD USA/12/118

S5.AAA In the band 155.5-158.5 GHz, the allocation to the Earth exploration-satellite (passive) and space research (passive) services shall terminate on 1 January 2018.

Reasons: This allocation will not be needed by passive sensors after the termination date. By the termination date, all passive sensors will have transitioned to the 148.5-151.5 GHz band.

ADD USA/12/119

S5.BBB The date of entry for the allocation to the fixed and mobile services in the band 155.5-158.5 GHz shall be 1 January 2018.

Reasons: Passive sensors require the use of this band until 1 January 2018.

ADD USA/12/120

S5.CCC Use of this allocation is limited to space-based radio astronomy only.

Reasons: This band is a likely candidate for a future space-based radio astronomy mission. No other space research use is contemplated.

ADD USA/12/121

S5.DDD The 81-81.5 GHz band is also allocated to the amateur and amateur-satellite services on a secondary basis.

Reasons: Amateur allocation

ADD USA/12/122

S5.EEE The band 75.5-76 GHz is also allocated to the amateur and amateur-satellite services on a primary basis until the year 200[6].

Reasons: Amateur allocation

ADD USA/12/123

S5.YYY Use of the bands 174.5-182 GHz by the inter-satellite service is limited to satellites in the geostationary-satellite orbit. The single-entry power flux-density, at all altitudes from 0 km to 1 000 km above the Earth's surface and in the vicinity of all geostationary orbital positions occupied by passive sensors, produced by a station in the inter-satellite service, for all conditions and for all methods of modulation, shall not exceed –144 dBW/m^2/MHz for all angles of arrival.

Reasons: This footnote is required to protect passive sensors operating in this band.

ADD USA/12/124

S5.XXX Use of the bands 116-123 GHz by the inter-satellite service is limited to satellites in the geostationary-satellite orbit. The single-entry power flux-density, at all altitudes from 0 km to 1 000 km above the Earth's surface and in the vicinity of all geostationary orbital positions occupied by passive sensors, produced by a station in the inter-satellite service, for all conditions and for all methods of modulation, shall not exceed –148 dBW/m^2/MHz for all angles of arrival.

Reasons: This footnote is required to protect passive sensors operating in this band.

ADD USA/12/125

RESOLUTION RAS

Use of the bands [ ] by the radio astronomy service

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that a large number of spectral lines of astrophysical interest above 71 GHz provide unique information about cosmic processes, such as the chemistry of the interstellar medium and the formation of stars and planets, and that this information cannot be obtained from any other source;

b) that Doppler shifted lines, which are also of great interest for astronomical studies, are found far removed from the rest frequency of some spectral lines and that highly Doppler shifted lines may offer the only means to obtain information about the very early universe and the formation of galaxies;

c) that mm-wave radio astronomy receivers are designed to cover substantial portions of the atmospheric windows above 70 GHz to take advantage of the information contained in spectral lines, as well as in continuum radiation;

d) that several administrations operate mm-wave radio astronomy observatories and that some are building or are planning to build a limited number of large new facilities to exploit the most advanced technologies; and that these facilities are intended to serve the needs of the worldwide scientific community;

e) that mm-wave observatories must be located on high mountain tops or plateaux to take advantage of the driest possible atmospheric conditions necessary to obtain high quality observations; and require substantial investments on behalf of the scientific communities concerned, and that therefore their number will remain low,

noting

that sharing between the radio astronomy service and other terrestrial services operating in bands above 71 GHz is facilitated by the natural attenuation provided by atmospheric gases, and that it can be further facilitated by adequate geographic separation,

urges

administrations to establish coordination zones around mm-wave radio astronomy sites operating in bands above 71 GHz. Coordination zone radii should be determined following the procedure outlined in Recommendation ITU-R RA.1031-1, separately for ground-based transmitters, airborne transmitters and transmitters that may be located on high altitude platforms (HAPS),

resolves

1 that in the frequency bands referred to in this Resolution, co-primary status of the radio astronomy service shall be recognized within coordination zones established by administrations. No coordination requirements should be imposed upon terrestrial services outside established coordination zones;

2 that in the bands referred to in this Resolution, co-primary services operating stations within a coordination zone should coordinate their operations with affected radio astronomy stations within five years of the date of notification of the radio astronomy site to the Radiocommunication Bureau.

Annex 1 lists the radio astronomy sites that operate, or plan to operate in the bands referred to in this Resolution as of [8 June 2000]. Observatories that operate only up to 92 GHz are identified with *** under the SITE column.

ADD USA/12/126

Reasons: RES RAS sets out the details of the limitation on the radio astronomy service. Annex 1 lists the observatories that operate in the radio astronomy service in bands shared with terrestrial services above 71 GHz at the time of WRC-2000.

[8] The Nobeyama site includes a 45 m diameter telescope, an interferometer that consists of six antennas of 10 m diameter, and a 60 cm diameter submillimeter telescope.

ADD USA/12/127

DRAFT RESOLUTION XXX (WRC-2000)

Consideration by a future world radiocommunication conference of issues dealing with sharing between passive and active services 71 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that the changes made to the Table of Frequency Allocations by WRC-2000 in bands above 71 GHz were based on the requirements known at the time of the Conference;

b) that the passive service spectrum requirements above 71 GHz are based on physical phenomenon and therefore are well known. These requirements are reflected in the changes made to the Table of Frequency Allocations by WRC-2000;

c) that several bands above 71 GHz are already used by EESS (passive) and SR (passive) because they are unique bands to measure specific atmospheric parameters;

d) that currently there is only limited knowledge of requirements and implementation plans for the active services to operate in bands above 71 GHz;

e) that in the past, technological developments have led to viable communication systems operating at increasingly higher frequencies and this can be expected to continue so as to make communication technology available in the future for the frequency bands above 71 GHz;

f) that in the future, there should be accommodation of alternative spectrum needs of the active and passive services when the new technologies become available;

g) that, following the revisions to the Table of Frequency Allocations by WRC-2000, sharing studies may be required for services in some bands above 71 GHz;

h) that interference criteria for passive sensors have been developed and are given in ITU-R SA.1029-1;

i) that sharing criteria for active and passive services in bands above 71 GHz have not yet fully developed within the ITU-R;

j) that, in order to ensure the protection of passive services above 71 GHz, WRC-2000 avoided co-allocations of active and passive services to prevent potential sharing problems,

recognizing

that to the extent practicable, the burden of sharing among active and passive services should be equitably distributed amongst the allocated services,

invites ITU-R

1 to continue its studies to determine if sharing is possible between active and passive services in the bands above 71 GHz;

2 to take into account the principles of burden sharing to the extent practicable in their studies;

3 complete the necessary studies, as soon as the technical characteristics of the active services in these bands are known;

4 develop recommendations specifying sharing criteria for those bands where sharing is feasible,

resolves

that a future competent conference should consider the results of ITU-R studies with a view to revising as appropriate the Radio Regulations in order to accommodate the emerging requirements of the active services taking into account the requirements of the passive services, in bands above 71 GHz,

instructs the Secretary-General

to bring this Resolution to the attention of the international and regional organizations concerned.

ADD USA/12/128

RESOLUTION YYY (WRC-2000)

Consideration by a future competent world radiocommunication conference of issues dealing with sharing between active services above 71 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-2000 made changes to the Table of Frequency Allocations above 71 GHz, following consideration of science service issues;

b) that there are several co-primary active services in some bands above 71 GHz in the Table of Frequency Allocations as revised by WRC-2000;

c) that there is limited knowledge of characteristics of active services that may be developed to operate in bands above 71 GHz;

d) that sharing criteria for sharing between active services in bands above 71 GHz have not yet been fully developed within ITU-R;

e) that sharing between multiple co-primary active services may hinder the development of each active service in bands above 71 GHz;

f) that the technology for some active services may be commercially available earlier than for some other active services;

g) that adequate spectrum should be available for the active services for which the technology is available at a later time,

noting

that sharing criteria need to be developed, to be used by a future conference, for determining to what extent sharing between multiple co-primary active services is possible in each of the bands,

resolves

1 that appropriate measures should be taken to fulfill the spectrum requirements for active services for which the technology is commercially available at a later time;

2 that sharing criteria be developed for co-primary active services in bands above 71 GHz;

3 that the sharing criteria developed should form a basis for a review of active service allocations above 71 GHz at a future conference, if necessary,

requests ITU-R

to complete the necessary studies with a view to presenting, at the appropriate time, the technical information likely to be required as a basis for the work of a future competent conference,

instructs the Secretary-General

to bring this Resolution to the attention of the international and regional organizations concerned.

Reasons: There is no consensus whether sharing between the passive services and the active services is feasible in many of the bands above 71 GHz. This is because there is a lack of information available on these active services in this frequency range. New Resolution XXX has been added which calls for ITU-R studies on sharing between active and passive services in bands above 71 GHz. Similarly, sharing conditions between many of the relocated active services above 71 GHz are not known and need to be developed and Resolution YYY calls for studies that can develop sharing criteria and should form a basis for a review of active service allocations above 71 GHz at a future conference, if necessary.

Proposals for agenda item 1.17

"to consider possible worldwide allocation for the Earth exploration-satellite (passive) and space research (passive) service in the band 18.6-18.8 GHz, taking into account the results of the ITU-R studies"

A proposal for worldwide allocation to the Earth exploration-satellite (passive) service in the band 18.6-18.8 GHz on a primary basis

Background information

At present, the allocations for the Earth exploration-satellite (passive) and the space research (passive) services in the band 18.6-18.8 GHz are on a primary basis in Region 2, but on a secondary basis in Regions 1 and 3.

The allocation to the Earth exploration-satellite (passive) service must be upgraded to primary status if the long-term ability to obtain environmental data with passive spaceborne sensors is to be preserved. Compatibility between the passive sensors and the fixed and fixed-satellite services requires adoption of constraints on the parameters of the fixed and fixed-satellite systems that use the band.

A pfd limit of –95 dBW/m^2 in a reference bandwidth of 200 MHz on geostationary systems in the fixed-satellite service will enable passive sensors to perform their mission if measurements are restricted to portions of the sensor orbit where the sensor is moving away from the Equator while taking sensor data over land masses. Additionally, allowing for an exceedance of this value by 3 dB for up to 5% of the time will allow the fixed-satellite service to implement power control in overcoming rain fades when needed.

Similarly, limiting the power delivered to any antenna of a station in the fixed service measured across the band 18.6-18.8 GHz to not exceed 0 dBW in 200 MHz along with an antenna pattern complying with Recommendation ITU-R F.699-4 will enable sharing with the fixed service.

MOD USA/12/129

18.6-22.21 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
18.6-18.8 EARTH EXPLORATION-SATELLITE (passive) FIXED FIXED-SATELLITE (space-to-Earth) MOD S5.523 MOBILE except aeronautical mobile ~~Earth exploration-satellite (passive)~~ Space research (passive) MOD S5.522	**18.6-18.8** EARTH EXPLORATION-SATELLITE (passive) FIXED FIXED-SATELLITE (space-to-Earth) MOD S5.523 MOBILE except aeronautical mobile SPACE RESEARCH (passive) MOD S5.522	**18.6-18.8** EARTH EXPLORATION-SATELLITE (passive) FIXED FIXED-SATELLITE (space-to-Earth) MOD S5.523 MOBILE except aeronautical mobile ~~Earth exploration-satellite (passive)~~ Space research (passive) MOD S5.522

Reasons: To establish a common worldwide primary allocation to the Earth exploration-satellite (passive) services to be used for environmental measurements.

MOD USA/12/130

S5.522 ~~In making assignments to stations in the fixed and mobile services, administrations are invited to take account of passive sensors in the Earth-exploration satellite and space research services operating in the band 18.6-18.8 GHz. In this band, administrations should endeavour to limit as far as possible both the power delivered by the transmitter to the antenna and the e.i.r.p. in order to reduce the risk of interference to passive sensors to the minimum.~~In the band 18.6-18.8 GHz, fixed and mobile service stations shall be limited to a total power delivered to each antenna of 0 dBW.

Reasons: To enable passive sensors and the fixed service to operate in the band without excessive interference to the sensors.

MOD USA/12/131

S5.523 ~~In assigning frequencies to stations in the fixed-satellite service in the direction space-to-Earth, administrations are requested to limit as far as practicable the power flux-density at the Earth's surface in the band 18.6-18.8 GHz, in order to reduce the risk of interference to passive sensors in the earth exploration-satellite and space research services.~~ The fixed-satellite service shall be limited to a power flux-density at the Earth's surface of –95 (dBW/m^2) across the 18.6-18.8 GHz band for all angles of arrival. This power flux-density limit may be exceeded by 3 dB for up to 5% of the time everywhere in the FSS service area. The use of this band by non-geostationary-satellite orbit fixed satellite service systems with apogees lower than 20 000 km shall be in accordance with the provisions of Resolution ZZZ (WRC-2000).

Reasons: To enable passive sensors and the fixed-satellite service to operate in the band without excessive interference to the sensors. Further, studies have not been completed to determine an allowable power flux-density limit on non-geostationary fixed-satellite service systems needed to protect Earth exploration-satellite service (passive).

ADD USA/12/132

DRAFT RESOLUTION ZZZ (WRC-2000)

Power flux-density limits applicable to non-GSO systems for protection of Earth exploration-satellite service (passive) in the band 18.6-18.8 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-2000 made changes to the Table of Frequency Allocations in the band 18.6-18.8 GHz;

b) that the power flux-density (pfd) limit in footnote **MOD S5.523** of the Radio Regulations was derived solely upon consideration of geostationary-satellite orbit fixed-satellite service systems and non-geostationary-satellite orbit fixed-satellite service systems with apogees higher than 20 000 km;

c) that initial sharing studies have indicated that low-Earth orbiting fixed-satellite service systems cause significantly greater interference into Earth exploration-satellite (passive) service sensors than do geostationary-satellite orbit fixed-satellite service systems;

d) that further sharing studies are required of the power flux-density limit applicable to non-geostationary-satellite orbit fixed satellite service systems operating with apogees below 20 000 km for the protection of Earth exploration-satellite (passive) service systems,

resolves

that non-geostationary-satellite orbit fixed-satellite service systems operating with apogees below 20 000 km shall do so only on a non-interference basis until an appropriate power flux-density limit is determined for protection of EESS (passive) systems,

invites ITU-R

to study, as a matter of urgency, the appropriate power flux-density values to be applied to non-geostationary-satellite systems in the 18.6-18.8 GHz band to ensure protection of the Earth exploration-satellite (passive) service without unduly constraining the development of either type of system, and submit the results to a future competent conference,

instructs the Secretary-General

to bring this Resolution to the attention of the international and regional organizations concerned.

Proposals for agenda item 1.19*bis*

"in accordance with Article **S14**, to consider objections expressed by administrations with respect to the Radio Regulations Board's Rules of Procedure relating to the application of RR **2674/S23.13** in order for the Bureau to modify its findings in accordance with the conclusions of the Conference"

Background Information

No**. S23.13 (RR2674)** states that, "in devising the characteristics of a space station in the broadcasting-satellite service, all technical means available shall be used to reduce, to the maximum, the radiation over the territory of other countries unless an agreement has been previously reached with such countries." No. **S23.13 (RR2674)** was adopted at WARC-71. It was intended as a statement of good engineering practice to reduce BSS interference with the terrestrial services outside of the intended service area.

At WRC-95, however, some countries sought to have the interpretation of No. **S23.13** (RR **2674**) revised to require, as a condition for registration, the approval of other countries within the service area of a BSS system proposed as a plan modification. After thorough debate, WRC-95 instructed the RRB to revise its Rules of Procedures to reflect the results of its debate. The decision reached by WRC-95 reflected a difficult compromise on the parts of all parties involved. The RRB made the revisions, but further concerns were raised at WRC-97. These concerns led WRC-97 to adopt Resolution **536** which resolves that: "in addition to observing No. **S23.13/2674**, and before providing satellite-broadcasting services to other administrations, administrations originating the services should obtain the agreement of those other administrations."

Still dissatisfied after a review of the RRB Rules for RR **S23.13** under the "review of finding" procedures of Article **S14**, the concerned countries persuaded the 1998 meeting of the ITU Council to adopt new agenda item 1.19*bis*.

NOC USA/12/133

Therefore, the United States is of the view that there is no need to repeat the work and discussion of WRC-95 and WRC-97, and that Resolution **536** and RR **S23.13** are sufficient. The United States proposes that WRC-2000 not revise the present Rule of Procedure for RR **S23.13/2674** to apply it retroactively, i.e. to BSS filings (under Article 4 of Appendix **S30** or under Resolution **33/S9**) made prior to 18 November 1995. The United States also supports the existing separation of Article 4 of Appendix **S30** and the Rule of Procedure for RR **S23.13/2674**.

Reasons: Agenda item 1.19*bis* has the effect of re-opening an issue that was resolved after much discussion first at WRC-95, and then at WRC-97 by the adoption of Resolution 536.

Proposals for agenda item 1.20

"to consider the issues related to the application of Nos. **S9.8, S9.9** and **S9.17** and the corresponding parts of Appendix **S5** with respect to Appendices **S30** and **S30A**, with a view to possible deletion of Articles **6** and **7** of Appendices **S30** and **S30A**, also taking into consideration Recommendation **35 (WRC-95)**"

A proposal for the modification of Appendix S30, Annex 1

Background information

Annex 1 to Appendix **S30** of the Radio Regulations specifies limits for determining whether a service is affected by a proposed modification to the BSS Plan (i.e. when it is necessary to seek the agreement of any other administration). Section 5 of Annex 1 specifies limits to the change in the pfd to protect the terrestrial services of administrations in Regions 1 and 3 from modifications to the Region 2 Plan. In particular, Section 5c) specifies the pfd limits for administrations in Region 1 east of longitude 30° E. Further, through Section 8a), the pfd limits in Section 5b) of Annex 1 apply to protect terrestrial services in Regions 1 and 3 from modifications to the Regions 1 and 3 BSS Plan.

This pfd limit is very stringent at low angles of elevation. For example, in order to meet this pfd limit the BSS spacecraft power must be significantly lower in areas of western Region 2 near Region 1 (e.g. Alaska) as compared to other areas in Region 2. As a result, the provision of BSS service to these areas requires larger BSS receive dishes, in some cases as large as 2.4 m. This will be the case for Region 2 administrations that propose to modify their Plan assignments to provide service to these areas.

The FCC requires provision of BSS service to Alaska when technically feasible. A relaxation in the pfd limit in Section 5c) of Annex 1 of Appendix **S30**, as proposed below, would allow the use of 60 cm BSS receive dishes in these areas for BSS service. ITU-R studied possible modifications to the limits in Sections 5b) and 5c) of Annex 1. Section 5.2.3.5 of the CPM Report contains a proposed change to these limits. Consistent with the CPM Report, the following changes to Section 5 of Annex 1 of Appendix **S30** are proposed:

APPENDIX S30

ANNEX 1

5 Limits to the change in the power flux-density to protect the terrestrial services of administrations in Regions 1 and 3[16]

MOD USA/12/134

b) in the frequency band 12.2-12.~~5~~7 GHz for territories of administrations in Regions 1[17] and 3 ~~and those in the western part of Region 1, west of longitude 30° E~~[18]:

–~~132~~148 dB(W/m^2/~~5 M~~4 kHz) for 0° ≤ γ < ~~10~~5°;

–~~132~~148 + ~~4.2~~0.5 (γ ~~– 10~~5) dB(W/m^2/~~5 M~~4 kHz) for ~~10~~5° ≤ γ < ~~15~~25°;

–~~111~~138 dB(W/m^2/~~5 M~~4 kHz) for ~~15~~25° ≤ γ < 90°;

Reasons: A relaxation in the pfd limit in Section 5c) of Annex 1 of Appendix S30, as proposed below, would allow the use of 60 cm BSS receive dishes in these areas for BSS service. This proposal is consistent with the CPM Report.

SUP USA/12/135

c)

Reasons: Due to the changes made to item "*b)*", this note is no longer required.

NOC USA/12/136

d) in the frequency band 12.5-12.7 GHz for all the territories of administrations of Regions 1[17] and 3:

–148 dB(W/m^2/4 kHz) for $\gamma = 0°$;

–148 + 4.6975 γ^2 dB(W/m^2/4 kHz) for $0° < \gamma \leq 0.8°$;

–142.5 + 25 log γ dB(W/m^2/4 kHz) for $\gamma > 0.8°$;

where γ is the angle of arrival of the incident wave above the horizontal plane, in degrees.

Reasons: Consequential number change.

Proposals for agenda item 2

"to examine the revised ITU-R Recommendations incorporated by reference in the Radio Regulations in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with principles contained in the Annex to Resolution **27 (Rev.WRC-97)"**

Proposals to modify Resolution 27 (Rev.WRC-97) and Resolution 28 (WRC-95)

Background information

Certain provisions of the Radio Regulations make specific reference to ITU-R recommendations. As the ITU-R recommendations are updated, it is necessary to determine if such references should be continued, suppressed, or updated citing the revised version of the applicable ITU-R recommendation.

Although the principle of Incorporation by Reference is widely supported by ITU members, its implementation in practice leads to various difficulties. It is important that administrations are aware of which recommendations could be candidates for incorporation by reference into the Radio Regulations. Also, administrations need to know of any ITU-R recommendation currently incorporated by reference, which are being (or have been) revised during the current study period. Administrations would benefit greatly by being advised of such recommendations well in advance of a WRC. Therefore, a mechanism for the early identification should be established.

In order to allow administrations as much time as possible to consult their experts and to consider the implications of updating references in the Radio Regulations, to reflect changes to Recommendations which are currently incorporated by reference, the approach outlined in 1) below is proposed. Similarly, to facilitate the work of administrations in their preparation for the possible introduction of new instances where recommendations may be incorporated by reference into the Radio Regulations, the approach outlined in 2) below is proposed.

1) Rather than have only the Radiocommunication Assembly (RA) communicate to the WRC a list of the ITU-R recommendations currently incorporated by reference in the Radio Regulations which have been revised and approved during the elapsed study period, the Director of the Radiocommunication Bureau should provide a report to the Conference Preparatory Meeting. This report would also include a listing of those ITU-R recommendations currently incorporated by reference which are being revised in preparation for the RA. This report would be for information only and would not confer any special status on the recommendations listed.

2) If a recommendation is not currently incorporated by reference into the Radio Regulations, it could only be considered for incorporation by reference if it is in response to a WRC agenda item.

MOD USA/12/137

RESOLUTION 27 (Rev.WRC-~~97~~2000)

References to ITU-R and ITU-T Recommendations in the Radio Regulations

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that the principles of incorporation by reference were adopted by the WRC-95 and have been revised by this Conference (see Annex 1 to this Resolution);

b) that there are provisions of the Radio Regulations which employ mandatory incorporation by reference but fail to make explicit reference to the ITU-R or ITU-T Recommendations incorporated;

MOD USA/12/138

c) that the 199~~7~~9 Conference Preparatory Meeting (CPM-~~97~~99) for this Conference urged administrations to give further consideration to the status of material incorporated by reference:

– using the initial assessment provided by the Radiocommunication Bureau in the CPM Report and the set of principles given in Annex 1 to this Resolution;

– noting that mandatory references shall be explicit and use the appropriate regulatory language;

– taking into account the factors set out in Annex 2 to this Resolution;

d) that the Director of the Radiocommunication Bureau has drawn up a list (see Annex 1 to the CPM Report to this Conference) of the provisions of the Radio Regulations using incorporation by reference, which provides an initial assessment of the status of each reference and forms the basis for the work on appropriate referencing, examples of which are contained in Annex 3 to this Resolution;

e) that the Bureau has drawn up a list, contained in Annex 4 to this Resolution, of the ITU-R Recommendations to which explicit reference is made in the Radio Regulations,

MOD USA/12/139

resolves

that ITU-R and ITU-T Recommendations incorporated or proposed for incorporation by reference in the provisions of the Radio Regulations be identified and examined at WRC-~~99~~[03], with a view to establishing the correct method of reference in accordance with the principles set out in Annex 1 to this Resolution and taking into account the factors listed in Annex 2 to this Resolution, in order to complete the simplification of the Radio Regulations in respect of incorporation by reference,

ADD USA/12/140

further resolves

that, in the case of ITU-R Recommendations which are not currently referenced in the Radio Regulations, only those Recommendations which are in response to a WRC agenda item can be considered for incorporation by reference,

MOD USA/12/141

instructs the Director of the Radiocommunication Bureau

to arrange for a review of the provisions of the Radio Regulations containing references to ITU-R or ITU-T Recommendations and propose suitable recommendations to the CPM-~~99~~[02] for inclusion in its Report to WRC-~~99~~[03], using the list of provisions contained in Annex 3 to this Resolution together with the guidance contained in Annexes 1 and 2 to this Resolution, and taking into account the list of ITU-R Recommendations contained in Annex 4 to this Resolution,

urges administrations

to use the CPM Report to WRC-~~99~~[03] in order to prepare their proposals on incorporation by reference to that Conference.

ANNEX 1 TO RESOLUTION 27 (Rev.WRC-~~97~~2000)

Principles of incorporation by reference

1 Where references are non-mandatory, it is not necessary to establish specific conditions in applying the texts quoted. In such cases, reference could, for example, be made to "the latest version" of a Recommendation.

2 Mandatory references to Resolutions or Recommendations of a world radiocommunication conference (WRC) are acceptable without restriction, since such texts will have been agreed by a WRC.

3 Where mandatory references are suggested, and the relevant texts are brief, the referenced material should be incorporated in the body of the Radio Regulations.

4 If, on a case-by-case basis, it is decided to incorporate material by reference on a mandatory basis, then the following provisions shall apply:

4.1 the referenced text shall have the same treaty status as the Radio Regulations themselves;

4.2 the reference must be explicit, specifying the specific part of the text (if appropriate) and the version or issue number;

4.3 the referenced text must be adopted by the Plenary of a competent WRC, but should not be part of the Final Acts;

4.4 all texts incorporated by reference must be readily available, by being published in a separate volume;

4.5 if, between WRCs, a referenced text (e.g. an ITU-R Recommendation) is updated, the reference in the Radio Regulations shall continue to apply to the original version until such time as a competent WRC agrees to incorporate the new version of the reference. The mechanism for considering such a step is given in Resolution **28 (WRC-~~95~~2000)**.

ANNEX 2 TO RESOLUTION 27 (Rev.WRC-~~97~~2000)

Factors to be considered for the further application of incorporation by reference

In reviewing the provisions of the Radio Regulations employing references to other texts, administrations and study groups should address the following factors:

1 whether each reference is of mandatory~~, i.e. incorporated by reference,~~ or non-mandatory character;

2 whether in existing non-mandatory references, or mandatory references which are determined to be of non-mandatory character, appropriate linking language is used, e.g. the words "should" or "may";

3 whether in existing mandatory references, or other types of reference which are determined to be of mandatory character, clear mandatory linking language is used, e.g. the word "shall";

4 whether the incorporated ITU-R or ITU-T Recommendation(s) are explicitly identified;

5 where referenced ITU-R or ITU-T Recommendations are not explicitly identified, determine which ones should be identified;

6 whether text incorporated from ITU-R or ITU-T Recommendations should be placed directly in the Radio Regulations instead of using incorporation by reference;

7 if the ITU-R or ITU-T Recommendation to be incorporated is, as a whole, unsuitable as treaty status text, whether to limit the reference to those portions of the ITU-R or ITU-T Recommendation which are of a suitable nature or to place the mandatory portion directly in the Radio Regulations.

Reasons: To clarify that, in the case of ITU-R Recommendations which are not currently referenced in the Radio Regulations, only those Recommendations which are in response to a WRC agenda item can be considered for incorporation by reference. Also, minor consequential editorial changes have also been identified.

MOD USA/12/142

RESOLUTION 28 (Rev.WRC-~~95~~2000)

Revision of references to ITU-R Recommendations incorporated by reference in the Radio Regulations

The World Radiocommunication Conference (~~Geneva, 1995~~Istanbul, 2000),

considering

a) that the Voluntary Group of Experts on simplification of the Radio Regulations (VGE) proposed the transfer of certain texts of the Radio Regulations to other documents, especially to ITU-R Recommendations, using the incorporation by reference procedure;

b) that, in some cases, the provisions of the Radio Regulations imply an obligation on Member States [‡] to conform to the criteria or specifications incorporated by reference;

c) that references to incorporated texts shall be explicit and shall refer to a precisely identified provision;

d) that, taking into account the rapid evolution of technology, ITU-R may revise the Recommendations incorporated by reference at short intervals;

e) that revised and approved Recommendations will not have the same legal force as the initial Recommendations, incorporated by reference until a competent world radiocommunication conference has so decided;

f) that it would be desirable to ensure, in the cases provided for in the Radio Regulations, that the provisions reflect the most recent technical developments,

ADD USA/12/143

noting

that Member States would benefit greatly from being advised, as early as possible, of which Recommendations have been revised and approved during the study period,

NOC USA/12/143*bis*

resolves

1 that each Radiocommunication Assembly shall communicate to the following world radiocommunication conference a list of the ITU-R Recommendations incorporated by reference in the Radio Regulations which have been revised and approved during the elapsed study period;

2 that, on this basis, the WRC shall examine those revised Recommendations, and decide whether or not to update the corresponding references in the Radio Regulations;

3 that, if the WRC decides not to update the corresponding references, ITU-R shall continue publishing the ITU-R Recommendations currently referenced in the Radio Regulations;

4 that WRCs shall place the examination of Recommendations in conformity with *resolves* 1 and *resolves* 2 of this Resolution on the agenda of future WRCs,

ADD USA/12/144

further resolves

5 to instruct the Director of the Radiocommunication Bureau to report to the CPM immediately preceding the WRC those ITU-R Recommendations already incorporated by reference in the Radio Regulations which have been revised and approved since the previous WRC, or which may be revised in time for the Radiocommunication Assembly;

6 that, in the case of ITU-R Recommendations which are not currently referenced in the Radio Regulations, only those Recommendations which are in response to a WRC agenda item can be considered for incorporation by reference,

NOC USA/12/144*bis*

urges administrations

to participate actively in the work of the Radiocommunication Study Groups and the Radiocommunication Assembly in the revision of those Recommendations to which mandatory references are made in the Radio Regulations.

Reasons: To establish a procedure to advise administrations, well in advance of a WRC, of those ITU-R Recommendations already incorporated by reference in the Radio Regulations which have been revised and approved since the previous WRC, or which may be revised in time for the Radiocommunication Assembly. Also to clarify that, in the case of ITU-R Recommendations which are not currently referenced in the Radio Regulations, only those Recommendations which are in response to a WRC agenda item can be considered for incorporation by reference. Minor consequential editorial changes have also been identified.

Proposals for agenda item 4

A proposal for the suppression of Resolution 63

Background information

A proposal for the suppression of Resolution 63; this Resolution is being suppressed because the work of TG 1/2 related to this Resolution has been completed.

SUP USA/12/145

RESOLUTION 63

Relating to the protection of radiocommunication services against interference caused by radiation from industrial, scientific and medical (ISM) equipment[1]

Reasons: TG 1/2 completed its work related to Resolution 63.

Plenipotentiary resolutions

in accordance with Resolution **95 (WRC-97)**, to review the resolutions and recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

Resolution 87 (Minneapolis, 1998) - Role of the notifying administration when acting as the notifying administration on behalf of a named group of administrations

Background information

The Administration of the United States, in particular as the notifying administration for INTELSAT, has considered any possible modifications to the Radio Regulations under Resolution **87**. This Administration has not experienced any difficulties either with other administrations acting as the notifying administration for a group of named administrations or acting as the notifying administration for INTELSAT. The Administration of the United States believes that the Radio Regulations are now adequate in this area and require no changes regarding the responsibilities of the notifying administration. The notifying administration and the intergovernmental organizations should retain the flexibility of making their own arrangements for interfaces with the ITU. Members of an intergovernmental organization responsible for satellite networks can best determine how it needs to comply with the Radio Regulations.

PART 8

Agenda item 7.2 - Agenda for future conferences

PART 8A

Agenda for WRC-[03] and WRC-[06]

1 Agenda for WRC-[03] - Modification of Resolution 722 (WRC-97)

Introduction

Agenda item 7.2 requests WRC-2000 to recommend to the Council items for inclusion in the agenda for the next WRC, and to give its view on the preliminary agenda for the subsequent conference and on possible agenda items for future conferences.

Proposals

Europe proposes that WRC-2000 suppresses Resolution 722 (WRC-97) and adopts Resolution NNN [EUR/13/10] (WRC-2000) as the agenda for WRC-[03] to be proposed for adoption by the Council.

SUP EUR/13/383

RESOLUTION 722 (WRC-97)

Preliminary agenda for the 2001 World Radiocommunication Conference

ADD EUR/13/384

RESOLUTION NNN [EUR/13/10] (WRC-2000)

Agenda for the 200[3] World Radiocommunication Conference

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that, in accordance with Nos. 118 and 126 of the Convention of the International Telecommunication Union (Geneva, 1992), the general scope of the agenda for a world radiocommunication conference should be established four years in advance and a final agenda shall be established two years before the conference;

b) Article 13 of the Constitution of the International Telecommunication Union (Geneva, 1992) regarding the competence and scheduling of world radiocommunication conferences and Article 7 of the Convention (Geneva, 1992) regarding their agendas;

c) the relevant Resolutions and Recommendations of previous world administrative radio conferences (WARCs) and world radiocommunication conferences (WRCs),

recognizing

a) that this Conference has identified a number of urgent issues requiring further examination by the 200[3] World Radiocommunication Conference (WRC-[03]);

b) that in preparing this agenda, many proposals from administrations could not be included and have had to be deferred to future conference agendas,

resolves

to recommend to the Council that a world radiocommunication conference be held in late 200[3] for a period of four weeks, with the following agenda:

1 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, taking account of the results of the 2000 World Radiocommunication Conference (WRC-2000), and with due regard to the requirements of existing and future services in the bands under consideration, to consider and take appropriate action in respect of the following topics:

1.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, taking into account Resolution **26** (**Rev.WRC-97**);

1.2 to consider the revision of Articles **S25** and **S19** and the rephrasing of Article **S1** of the ITU Radio Regulations concerning the amateur and amateur-satellite services;

Reasons: Modernization of the regulations concerning amateur radio (Article S25) is generally supported by administrations and all three Regions of the International Amateur Radio Union (IARU). To take account of this modernization some administrations already have practices that are not in accordance with the existing stipulations of the Radio Regulations, e.g. formation of amateur call signs as defined in Article S19. The proposed changes will take account of the need for improvement, simplification and adaptation in the technical and legal conditions related to the amateur service This may require related changes in Article S1 and other relevant parts of the RR.

1.3 issues related to Appendix **S3**:

1.3.1 to consider the results of studies regarding the boundary between spurious and out-of-band emissions;

Reasons: Task Group 1/5 has studied the issue of the definition of the boundary between OOB and spurious emission and will come up with solutions to define the boundary in October 2000. This will need to be reflected in Appendix S3.

1.3.2 to consider the results of studies and to propose any regulatory measure regarding the protection of passive services and safety services from unwanted emissions, in particular from space services transmissions, in response to *recommends* 7 and 8 of Recommendation **66** (**Rev.WRC-97**);

Reasons: ITU-R, in preparation of the WRC-2000 agenda item 1.2, have concluded that the “design objectives” for satellite services’ spurious emission limits in Appendix S3 should be reconfirmed as definitive limits. This conclusion was based on the technical feasibility for space services to comply with these limits. However, ITU-R has pointed out that there are clear indications that in many instances, safety and passive services do not receive adequate protection against unwanted emissions.

ITU-R is studying the means of providing additional, necessary protection against unwanted emissions for safety and passive services beyond that given in Appendix S3. These studies should enable to respond to Recommendation 66 (Rev.WRC-97) (particularly *recommends* 7 and 8).

1.3.3 to consider the inclusion of general limits for out-of-band emissions in the Radio Regulations, in particular with regard to whether it is appropriate to do so, taking into account the results of ITU-R studies;

Reasons: Task Group 1/5 is developing a new Recommendation specifying safety limits for OOB emissions. This agenda item was proposed for giving WRC-03 the opportunity to assess whether there would be any interest in including these limits in the RR.

1.4 review the frequency and channel arrangements in the MF and HF bands by the maritime-mobile service, with a view to meeting the changing needs of this service and the introduction of digital technology and taking into account Resolution **347 (WRC-97)**;

review the use of the HF bands by the aeronautical mobile (R) service with a view to meeting the changing needs of this service.

Reasons: At the time of WRC-03 the GMDSS will have been operational for a number of years. Sufficient experience will have been gained about the consequences of GMDSS and other recent developments affecting the use of frequencies on MF (415-526.5 kHz and 1 606.5-3 800 kHz) and HF bands. Many countries are in the process of reviewing the activities of their commercial coast stations. New developments in the field of satellite services will also influence the use of MF and HF bands.

1.5 to consider the status of allocations to the radiolocation and other services in the bands 2 900-3 100 MHz and around 5.5 GHz;

Reasons: To possibly upgrade the radiolocation service from secondary status to primary status in the band 2 900-3 100 MHz and around 5.5 GHz and to give WRC-03 the opportunity to consider the outcome of studies carried out by ITU-R on the possibility of introducing mobile applications in these bands and particularly around 5.5 GHz, according to proposed agenda item 1.9.

1.6 to consider Appendix **S13** and Resolution **331 (Rev.WRC-97)** with a view to their deletion and, if appropriate, consider related changes to Chapter **SVII** and other provisions of the Radio Regulations as necessary, taking into account the implementation of the Global Maritime Distress and Safety System (GMDSS) and the possibility of its application to ships not subject to SOLAS regulations;

Reasons: WRC-97 decided that the listening watch on 2 182 kHz remains mandatory until 1 February 1999, but some ship and coast stations continue maintaining watch on a voluntary basis. The IMO Maritime Safety Committee at its 69th meeting (May, 1998) agreed that the mandatory listening watch on channel 16 on board SOLAS ships ceases on 1 February 2005. The continuing implementation of GMDSS on an increasing number of non-SOLAS vessels makes it necessary to review the provisions of Appendix S13 and Chapter SVII together with the related Resolution 331 (Rev.WRC-97) in good time before 2005. The IMO in its opinion to WRC-2000 on this matter strongly recommends that this item be retained on the final agenda of WRC-03.

1.7 to consider the results of studies, and take necessary actions relating to:

1.7.1 the exhaustion of the maritime-mobile service identity numbering resource (Resolution **344 (WRC-97)**);

Reasons: It is evident that the MMSI numbers are a scarce resource. ITU-R studies performed in accordance with Resolution 344 may reveal means of extending this resource or identifying new resources.

1.7.2 shore-to-ship distress communication priorities (Resolution **348 (WRC-97)**);

Reasons: This item is in accordance with Resolution 348 (WRC-97).

1.8 consideration of the need to realign the allocations to the amateur, amateur-satellite and broadcasting services around 7 MHz on a worldwide basis, taking into account Recommendation **718 (WARC-92)**;

Reasons: Recommendation 718 has already been awaiting implementation for eight years. Therefore, the purpose of this proposal is to satisfy this Recommendation and reasons stated therein such as different allocations in ITU Regions, large disparity in power levels between amateur and broadcasting services and consequential incompatibility. In addition, others reasons are:

– to meet the ITU objective of harmonization of allocations on a worldwide basis;

– to ensure globally harmonized, satisfactory spectrum access around 7 MHz for the amateur, broadcasting, fixed and mobile services;

– to remove the long-lasting uncertainty concerning the future of this part of the spectrum to facilitate planning and efficient spectrum utilization.

Since WARC-92 significant changes have occurred that make the issue even more pressing. The main users of HF fixed and mobile links in Europe find that their usage below 10 MHz has increased; so much so that extensive sharing between the amateur service and the fixed/mobile services could no longer offer a satisfactory solution for either service. Also, there needs to be more of a balance between the fixed and mobile spectrum available above and below 7 MHz. Pressure on the available spectrum for HF broadcasting below 10 MHz has also increased over the last few years as a result of a more cooperative political environment and economic factors, both of which have combined to increase the use of medium range single hop transmissions for programme delivery.

Studies are therefore continuing on the basis that:

- there is no real distinction between fixed and mobile equipment and use so that allocations in the frequency allocation table should be made generic;
- congestion in the broadcasting bands between 4 and 7 MHz continues the recent trend towards single hop, lower frequency coverage, as a result of greater sharing of broadcasting facilities between countries.

1.9 consider the allocation of frequencies to the mobile service in the frequency ranges 5 150-5 350 MHz and 5 470-5 725 MHz;

Reasons: To gain global harmonized frequency allocations to the mobile service in support of radio local area networks (RLAN) applications, including HIPERLANs, on a worldwide basis, while ensuring the protection and on-going operations of existing services.

The band 5 150-5 350 MHz is already nationally used for RLAN in many countries and the global MS allocation would give RLANs an appropriate ITU allocation status.

Studies in ETSI and CEPT have indicated that 320-330 MHz spectrum is needed for RLANs at 5 GHz band, then the 5 150-5 350 MHz could not alone be sufficient. Also, this band is shared with other services, which limits the RLAN use indoors. The bands 5 470-5 725 MHz could fulfil the RLAN requirement. Studies in CEPT have proved that sharing with existing services in the band 5 470-5 725 MHz can be arranged.

RLANs are widely seen as complementing the picture of Mobile Information Society together with cellular networks, taking care of the broadband data traffic in offices and other hot spots. A global allocation would help this scenario, make the global circulation of equipment easier and facilitate the benefits of economy of scale.

ISM band at 5 GHz is not preferred due to the expected significant increase of the use of other applications in this band and the high quality of service requirement for RLANs.

1.10 review of spectrum and regulatory requirements to facilitate emerging terrestrial wireless interactive multimedia applications in accordance with Resolution [**EUR/13/12**] **(WRC-2000)**;

Reasons: Wireless mobile multimedia applications are not defined by ITU-R, but are regarded to be end-user radio connection(s) to core networks, where core networks include, for example, PSTN, ISDN, PLMN, PSDN, Internet, WAN/LAN, CATV, etc. Although a wireless mobile multimedia application in itself is not a service, it can clearly be provided within the radio services FS, MS, and BS, as defined by the Radio Regulations.

To respond to the rapid convergence of technologies, the Radio Regulations need to address this issue.

To allow for a progressive allocation of spectrum required for new applications and to satisfy Universal Services as to obtain:

- flexibility;
- instant implementation;
- worldwide use; and
- a reduction of the regulatory constraints.

1.11 add a primary allocation to the fixed service in the band 17.3-17.7 GHz for Region 1 in Article **S5** of the RR;

Reasons: In Region 1, the only primary service allocated in the band 17.3-17.7 GHz is the FSS (Earth-to-space). This band is considered of significant interest for point-to-point and point-to-multipoint systems in the fixed service.

1.12 to consider regulatory provisions and possibly identification of spectrum above about 19.7 GHz for high density systems in the fixed-satellite service;

Reasons: Many FSS bands have been shared with the FS, which has worked well with a limited number of terminals for both types of service.

In recent years, many of these shared bands are being identified for HDFS use, often involving Fixed Wireless Access, Multimedia Wireless services, etc.

As a consequence, many bands available for future HDFSS use are becoming more difficult to share.

There are exclusive FSS bands (without the FS) for the possible use of HDFSS in the range 10-30 GHz. Taking Region 1 as an example, these bands amount to 1.5 GHz in total, and they will be used in the first generations of interactive satellites, leaving no room for expansion of the high density use of the fixed-satellite service in the exclusive FSS bands.

There is a need to provide more spectrum for one-way or two-way services via satellites and for global harmonization of satellite spectrum, also for GSO satellites.

It should be noted that satellite systems in general have a longer preparation time than terrestrial systems, and that spectrum availability is a condition for the large investments needed for satellite systems. Furthermore, obtaining the required capital to initiate a space system in a new band requires a certainty that the band will be available across the whole of the coverage area when the network is brought into use. If there is a diversity of usage allowed in the countries within the coverage area, with HDFSS allowed in only some of the area, then this would result in sub-optimum efficiency in the use of the spectrum. It is exceedingly difficult and expensive if it is necessary to change the frequency usage for a satellite network once the design has been started.

Consideration thus must be made to ensuring that a sufficiently wide allocation (500-1 000 MHz for uplink as well as for downlink in the 20/30 GHz range and 1-2 GHz in each direction in the 40/50 GHz range) in addition to that presently available is established for HDFSS on a global basis.

This matter has been considered by the CPM in sections 4.2, 6.1.2, 6.1.4 and 6.1.5 of the Report.

1.13 review of the usage of the band 13.75-14 GHz for all services, in accordance with Resolution **[EUR/13/13] (WRC-2000)**, with a view to improve sharing conditions for FSS;

Reasons: The 13.75-14 GHz band is shared by the FSS and the radiolocation and radionavigation services and certain limitations have been placed on the FSS, radiolocation and radionavigation service in No. S5.502. The band is also shared with the Space Research Service, on a secondary basis, under the conditions set out in provision Nos. S5.503 and S5.503A.

The FSS operators have expressed interest in operating small earth station terminals in this band. In order to accommodate this request, the constraints regarding the minimum antenna diameter (and e.i.r.p. levels) of FSS earth stations stated in No. S5.502 have to be re-examined for the possible identification of alternative sharing conditions that would continue to ensure the protection of the radiolocation service.

Europe is already proposing suppression of the constraint on minimum e.i.r.p. for FSS under agenda item 1.13.1. Studies have been initiated within ITU-R to determine whether some other constraints on FSS could be alleviated.

1.14 to consider the results of studies related to Resolution **114 (WRC-95)**, dealing with the use of the band 5 091-5 150 MHz by the fixed-satellite service (Earth-to-space) (limited to feeder links of the non-geostationary mobile-satellite service), and review the allocation to the aeronautical radionavigation service and the fixed-satellite service in the frequency band 5 091-5 150 MHz;

Reasons: WRC-95, by the means of Resolution 114, resolved:

"that the allocation to the aeronautical radionavigation service and the fixed-satellite service in the frequency band 5 091-5 150 MHz should be reviewed at WRC-01".

WRC-95, by the means of Resolution 114, required ITU-R "to study the technical and operational issues relating to sharing of this band between the aeronautical radionavigation service and the fixed-satellite service providing feeder links of the non-GSO mobile-satellite service (Earth-to-space)" and "to bring the results of these studies to the attention of WRC-01".

WRC-95 invited ICAO "to further review, within the same time-frame, detailed spectrum requirements and planning for international standard aeronautical radionavigation systems in the above-mentioned band".

It is appropriate that WRC-[03] review the allocations in the band 5 091-5 150 MHz and takes on board a requirement to WRC-01 by WRC-95.

1.15 revise **APS30** and **APS30A** in accordance with the decisions of WRC-2000;

Reasons: Facilitate Council Resolution 1129.

1.16 to consider possible changes to the procedures for the advance publication, coordination and notification of satellite networks in response to Resolution 86 (Minneapolis, 1998);

2 to consider outstanding items from WRC-2000:

2.1 to consider results of ITU-R studies on the feasibility of sharing in the band 2 700-2 900 MHz between the aeronautical radionavigation service and the mobile service carried out in accordance with Resolution **[EUR/13/1] (WRC-2000)** and take appropriate action on this subject;

2.2 to consider any additional changes to Appendix **S18** to enable the use of digital communications by the maritime-mobile service, taking into account Resolution **342 (Rev.WRC-2000)**;

2.3 on the basis of the results of the technical, operational and regulatory studies conducted in accordance with Resolution **[EUR/13/5] (WRC-2000)**:

2.3.1 to review and, if appropriate, revise the provisional pfd limits concerning the operation of RNSS (space-to-Earth) systems in the frequency bands 1 151-1 300 MHz in order to ensure that the RNSS (space-to-Earth) will not cause harmful interference to the aeronautical radionavigation, the radionavigation and the radiolocation services;

2.3.2 to consider compatibility between RNSS and ARNS in the band 960-1 215 MHz;

2.4 to consider, on the basis of the results of the studies in accordance with Resolution **130 (Rev.WRC-2000)**, the inclusion of power limits or other frequency sharing mechanisms among GSO, non-GSO and terrestrial systems;

2.5 to consider regulatory provisions for high altitude platform stations in the bands 47.2-47.5 GHz and 47.9-48.2 GHz and possible additional frequency allocations for such high altitude platform stations in the fixed service in the range 18-32 GHz taking into account the results of ITU-R studies conducted in accordance with Resolution **122 (Rev.WRC-2000)**;

2.6 to consider whether earth stations located on board vessels could operate in fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz taking into account the results of the regulatory, technical and operational studies conducted in accordance with Resolution **[EUR/13/8] (WRC-2000)**;

3 to examine the revised ITU-R Recommendations incorporated by reference in the Radio Regulations which have been communicated by the 2001 Radiocommunication Assembly, in accordance with Resolution **28 (WRC-95)**; and decide whether or not to update the corresponding references in the Radio Regulations, in accordance with the principles contained in the Annex to Resolution **27 (Rev.WRC-97)**;

4 to consider such consequential changes and amendments to the Radio Regulations as may be necessitated by the decisions of the Conference;

5 in accordance with Resolution **95 (WRC-97)**, to review the Resolutions and Recommendations of previous conferences with a view to their possible revision, replacement or abrogation;

6 to review, and take appropriate action on, the Report from the Radiocommunication Assembly submitted in accordance with Nos. 135 and 136 of the Convention (Geneva, 1992);

7 to identify those items requiring urgent action by the radiocommunication study groups;

8 in accordance with Article 7 of the Convention (Geneva, 1992):

8.1 to consider and approve the Report of the Director of the Radiocommunication Bureau on the activities of the Radiocommunication Sector since WRC-2000;

8.2 to recommend to the Council items for inclusion in the agenda for the [2006] World Radiocommunication Conference,

invites the Council

to finalize the agenda and arrange for the convening of WRC-[03] and to initiate as soon as possible the necessary consultation with Member States,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a Report to WRC-[03],

instructs the Secretary-General

to communicate this Resolution to concerned international and regional organizations.

2 Preliminary agenda for WRC-[06]

Introduction

Agenda item 7.2 requests WRC-2000 to recommend to the Council items for inclusion in the agenda for WRC-[03], and to give its view on the preliminary agenda for the [2006] Conference and on possible agenda items for future conferences.

Proposal

Europe proposes that WRC-2000 adopt the preliminary agenda for WRC-[06] for consideration by the next Council.

ADD EUR/13/385

RESOLUTION [EUR/13/11] (WRC-2000)

Preliminary agenda for the [2006] World Radiocommunication Conference

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that, in accordance with Nos. 118 and 126 of the Convention of the International Telecommunication Union (Geneva, 1992), the general scope of the agenda for the [2006] World Radiocommunication Conference (WRC-[06]) should be established four years in advance;

b) Article 13 of the Constitution of the International Telecommunication Union (Geneva, 1992) regarding the competence and scheduling of world radiocommunication conferences and Article 7 of the Convention (Geneva, 1992) regarding their agendas;

c) the relevant Resolutions and Recommendations of previous world administrative radio conferences (WARCs) and world radiocommunication conferences (WRCs),

resolves to give the view

that the following items should be included in the preliminary agenda of WRC-[06], to be held in late [2006]:

1 to take appropriate action in respect of those urgent issues that were specifically requested by the [2003] World Radiocommunication Conference (WRC-[03]);

2 on the basis of proposals from administrations and the Report of the Conference Preparatory Meeting, and taking account of the results of WRC-[03], to consider and take appropriate action in respect of the following topics:

2.1 requests from administrations to delete their country footnotes or to have their country name deleted from footnotes, if no longer required, taking into account Resolution **26 (Rev.WRC-97)**;

2.2 to consider the development of appropriate arrangements in order to facilitate global circulation for carriage and use of radiocommunication terminals;

Reasons: It is clear that global circulation cannot be allowed for all kinds of terminals. In many cases the circulation needs to be restricted. Reasons for restriction can be e.g. that frequency or site clearance is necessary in order to avoid interference.

Taking into account the aforementioned considerations, it should be recognized that in recent years good experience has been gained from implementation of mechanisms allowing for CEPT-wide circulation of various radio terminals. With the examples of GSM, S-PCS and in the future also IMT-2000, services are now extending beyond countries and regions.

This proposed agenda item is aiming at securing the successful development of systems on a worldwide basis by providing means to facilitate global circulation of their terminals.

2.3 to review the allocations for the HF services taking account of the impact of new modulation and adaptive control techniques and any recommendations by WRC-[03] on the adequacy of the frequency allocations for HF broadcasting from about 4 MHz to 10 MHz and on the future use and requirements of the aeronautical mobile (R) and maritime-mobile services;

Reasons: WRC-03 may be expected to recommend changes to the current allocations to the HF services as a result of the examination of several items related to the HF services already included on the preliminary agenda for WRC-03. There will therefore be a need for consequential changes at WRC-05 to implement any recommended changes coming out of WRC-03.

This is in line with PP-98 Resolution 80 which, in order to improve the efficiency of WRCs, requires WRC agendas to be set in two conference cycles so that the preliminary work of one WRC is brought to a swift conclusion by the following WRC.

The preliminary agenda item 2.12 for WRC-03 included in Resolution 722 (WRC-97), may result in a substantial rearrangement of the present allocations to the HF services around 7 MHz. In particular, the solution achieved for the realignment around 7 MHz will have a direct impact on the work related to WRC-03 agenda item 2.13 on the future spectrum requirements in the range 4-10 MHz. Should WRC-03 confirm the need for additional spectrum for HFBC and identify 7 MHz as one of the bands for this possible expansion, then this together with any rearrangement resulting from agenda item 2.12 will need to be taken into account at a future WRC.

Other WRC-03 topics involving HF services include item 3.6 on the use of adaptive systems in the MF/HF bands, and studies into the needs of the aeronautical mobile (R) and maritime-mobile services undertaken in response to preliminary agenda item 2.4 and the agenda item 8.4 deferred from WRC-2000. (NOTE - A separate proposal addresses the merging of the two items regarding the mobile services.)

In addition, specific proposals directly related to the amateur and fixed services may emerge from WRC-03 for consideration by WRC-05. It is therefore appropriate to provide for a preliminary agenda item for WRC-05 referring to the need for a review of the allocations to the services involved following on from the work at WRC-03. The scope of the work will have to be kept under review in order to accommodate further development of the provisional WRC-03 agenda in respect of HF services.

2.4 consider possible changes to the procedures for the advance publication, coordination and notification of satellite networks in response to Resolution 86 (Minneapolis, 1998),

invites the Council

to consider the views given in this Resolution,

instructs the Director of the Radiocommunication Bureau

to make the necessary arrangements to convene meetings of the Conference Preparatory Meeting and to prepare a Report to WRC-[06],

instructs the Secretary-General

to communicate this Resolution to concerned international and regional organizations.

Proposals submitted by the following administrations

Germany, Austria, Bosnia and Herzegovina, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Liechtenstein, Norway, Netherlands, Portugal, San Marino, Slovenia, Sweden, Switzerland, Turkey

PART 8B

Additional resolutions for future conferences

1 Review of service definitions in light of technology convergence

Introduction

The objective of this proposed new agenda item to the next competent WRC, illustrated by Resolution [EUR/13/12] (WRC-2000), is to provide suggested review of spectrum and regulatory requirements as guidance for administrations wishing to implement new terrestrial wireless interactive multimedia applications, taking due account of sharing and harmonization issues, and the possible widespread worldwide use. Both traditional telephony applications as well as wireless interactive multimedia applications should be considered.

Terrestrial wireless interactive multimedia applications are not defined by ITU-R, but are regarded to be end-user radio connection(s) to core networks. Although a terrestrial wireless interactive multimedia application in itself is not a service, it can clearly be provided within the radio services fixed (FS), mobile (MS), and broadcasting (BS), as defined by the Radio Regulations.

It can be foreseen that new wireless mobile multimedia applications will show an extraordinary expansion and that they will comprise multiple services, including FS and BS. The potential for terrestrial wireless interactive multimedia applications to enhance the availability of telecommunications services in both developing and developed countries is substantial.

The present procedure for establishing and approving of WRC agendas is far too slow, as compared with the progress of technology and could be to the detriment of development. The inclusion, in the agenda of each WRC, of a standing agenda item, calling for a review of the spectrum requirement for these emerging terrestrial wireless interactive multimedia applications would facilitate:

- simpler, efficient planning of the spectrum;
- simpler administration of frequency allocations and the accommodation of market/technology evolution;
- faster deployment of new services due to reduced administrative burdens;
- equitable treatment of operators worldwide;
- the encouragement of innovative technologies in a less prescriptive and more flexible regulatory regime.

Proposal

The above-mentioned administrations suggest that WRC-2000 adopt the proposed Resolution [EUR/13/12] (WRC-2000), which would enable ITU to review spectrum and regulatory requirements to facilitate implementation of emerging terrestrial wireless interactive multimedia systems and to respond to the rapid convergence of technologies in a timely manner.

ADD EUR/13/386

RESOLUTION [EUR/13/12] (WRC-2000)

Review of spectrum and regulatory requirements to facilitate emerging terrestrial wireless interactive multimedia applications

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) the rapid technical evolution in several areas of telecommunications;

b) the importance of finding global solutions for new terrestrial wireless interactive multimedia applications;

c) the need for terrestrial wireless interactive multimedia applications to individual end-users;

d) the convergence between services using digital formats (such as fixed, mobile and some broadcasting applications);

e) the need for worldwide allocations to such services also calling for higher spectrum efficiency;

f) the benefit, also for developing countries, when applying new, globally harmonized equipment and spectrum allocations for the implementation of market driven universal services,

noting

a) the historical based frequency segmentation, particularly the differences between Regions, but also the segmentation between services, of the Table of Frequency Allocations (Article **S5** of the Radio Regulations);

b) Recommendation **34 (WRC-95)**, which was derived from the recommendations of the Voluntary Group of Experts (VGE) to study alternative allocation methods, merging of services, etc., and which set the objectives to allocate frequency bands on a worldwide basis and to the most broadly defined services, wherever possible,

also noting

c) Resolution 9 of the World Telecommunication Development Conference (Valetta, 1998), calling for an active participation by the developing countries to review the global spectrum requirements for new technologies;

d) the new ITU-R Question 221/9 pertaining to spectrum vision for the fixed [and mobile] service[s];

e) ITU-R Study Group 8 [Question xxx/8] [Recommendation M.YYY] is currently addressing the relevant issues,

resolves

that competent WRCs include in their agendas an item to review spectrum and regulatory requirements to facilitate implementation of emerging terrestrial wireless interactive multimedia applications to respond to the convergence of technologies, in order to enable future conferences to make suitable allocations in a timely manner, to meet new requirements of new and emerging technological developments in the fixed, mobile and broadcasting services,

requests ITU-R

to pursue its studies in this area, in order to assist in the development of common, worldwide fixed and mobile allocations suitable for such new terrestrial wireless interactive multimedia technologies and applications, and to report its conclusions in time for the next competent WRC,

invites administrations

to participate in these studies and to bring proposals to future WRCs to meet the above.

Reasons: To allow for a progressive allocation of spectrum required for new applications and to satisfy universal services as to obtain:

- flexibility;
- instant implementation;
- worldwide use; and,
- a reduction of the regulatory constraints.

2 Sharing between FSS and radiolocation services

Introduction

The constraints under which FSS and radiolocation services are allowed to share the 13.75-14 GHz band need to be reviewed and possibly revised.

The ITU-R is invited to continue its studies to allow WRC-[03] to consider adopting alternative sharing constraints, more in line with today's technological advances and market demand for services.

Proposal

Europe proposes that WRC-2000 adopt the following Resolution which would facilitate sharing between FSS and radiolocation services.

ADD EUR/13/387

RESOLUTION [EUR/13/13] (WRC-2000)

Sharing between FSS and radiolocation in the band 13.75-14 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WARC-92 (Malaga-Torremolinos) added an allocation to the fixed-satellite service (FSS) in the band 13.75-14 GHz;

b) that this band is shared with the radiolocation and radionavigation services and certain limitations have been placed on the fixed-satellite, radiolocation and radionavigation services in provision No. **S5.502**;

c) that this band is also shared with the space research service, on a secondary basis, under the conditions set out in provisions Nos. **S5.503** and **S5.503A**;

d) that the FSS operators have expressed interest in operating small earth station terminals in the band 13.75-14 GHz;

e) that there is a need for the continued protection of the radiolocation service,

resolves

to invite ITU-R

1 to conduct studies prior to WRC-[03] to consider the sharing conditions stated in footnotes Nos. **S5.502** and **S5.503** with a view to reviewing the constraints regarding the minimum antenna diameter and e.i.r.p. levels of FSS earth stations in No. **S5.502** while continuing to ensure the protection of the radiolocation;

2 to identify alternative sharing conditions that could allow sharing between FSS, radiolocation and other services.

Reasons: The 13.75-14 GHz band is shared by the FSS and the radiolocation and radionavigation services and certain limitations have been placed on the FSS, radiolocation and radionavigation service in No. S5.502. The band is also shared with the space research service, on a secondary basis, under the conditions set out in provisions Nos. S5.503 and S5.503A.

The FSS operators have expressed interest in operating small earth stations terminals in this band. In order to accommodate this request, the constraints regarding the minimum antenna diameter (and e.i.r.p. levels) of FSS earth stations stated in No. S5.502 have to be re-examined for the possible identification of alternative sharing conditions that would continue to ensure the protection of the radiolocation service.

Europe is already proposing suppression of the constrain on minimum e.i.r.p. for FSS under agenda item 1.13.1. Studies have been initiated within ITU-R to determine whether some other constraints on FSS could be alleviated.

PLENARY MEETING

EUROPEAN COMMON PROPOSALS FOR THE WORK OF THE CONFERENCE

PART 7

APPENDICES S3 AND S7, RESOLUTIONS 28 (WRC-95) AND 95 (WRC-97), PP-98 RESOLUTIONS

CONTENTS

Proposals submitted by the following administrations

Germany, Austria, Bosnia and Herzegovina, Croatia, Denmark, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Norway, Netherlands, Portugal, San Marino, Slovenia, Sweden, Switzerland, Turkey

PART 7D

Agenda item 7.1 - Report of the Director, BR

PART 7D2

Rules of Procedure - Resolution 80 (WRC-97)

Add the following text at the end of Part 7D of the European common proposals.

1 Background

Europe has noted the attempts by the Radio Regulations Board to prepare some draft Rules of Procedure in response to Resolution 80. In Document CMR2000/29, the RRB have suggested to the WRC some possible additions No. S11.44*bis* and No. S11.48*bis* which would have the effect of increasing the time period to bring satellite frequencies into use.

In reviewing the suggestions made by the RRB, Europe would like to recall that one of the few improvements made by WRC-97 following the Resolution 18 (Kyoto, 1994) review was the shortening of the time frame for the bringing into use of satellite networks. The suggestions put forward by the RRB in Document CMR2000/29 go counter to the improvements that were made at WRC-97. Consequently, Europe cannot support proposals of this type for the following reasons:

- these proposals negate the improvements made by WRC-97;
- the final decisions of WRC-97 were to have a 5-year period with a 2-year extension subject to very specific conditions. At the time of WRC-97 an extension of 3 years was also considered but not accepted by the WRC;
- any extension on an exceptional basis will probably result in the extension being applied almost universally;
- the delay in processing should not be a factor in determining what the time limit for the bringing into use of satellite networks should be. If it were the case then there would be different time limits for different networks as the BR delay varies with time and administrations would not know in advance what the time period is. In addition, there are other measures being proposed to deal with the backlog problem.

2 Proposal

NOC EUR/13/376

S11.44
to
S11.44I

Reasons: In response to Resolution 80 (WRC-97), there shall be no increase in the time periods of Article S11 to bring satellite frequencies into use.

Proposals submitted by the following administrations

Germany, Austria, Bosnia and Herzegovina, Croatia, Denmark, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Norway, Portugal, San Marino, Slovenia, Sweden, Switzerland, Turkey

PART 7D3

Rules of Procedure - S5.488

Add the following at the end of Part 7D of the European common proposals:

Introduction

Section 7.6 of the CPM Report discusses the regulatory situation resulting from the modification of footnote S5.488 by WRC-97 and the associated RoP adopted by the RRB at its 13th meeting 6-14 July, Geneva, 1998 which became effective as from 1 January 1999.

Europe considers that in order to bridge the apparent regulatory gap resulting from this situation, there is a need to establish an appropriate regulatory mechanism by which the terrestrial service sharing the same frequency band with the space service, on an equal basis, are to be adequately protected.

The CPM Report identified three approaches to this effect:

Approach 1: The introduction of hard pfd limits for Region 2 GSO FSS networks, similar to those currently in Article **S21**;

Approach 2: The introduction of pfd values which are thresholds;

Approach 3: Existing provision **S5.488** might be modified to refer explicitly to **S9.21**.

Europe considers that the most appropriate method to resolve this situation is the adoption of Approach 1. The following proposals are made in this respect:

MOD EUR/13/377

S5.488 The use of the bands ~~11.7-12.2 GHz by the fixed-satellite service in Region 2 and~~ 12.2-12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems.~~ The use of the band 11.7-12.2 GHz by the fixed-satellite service in Region 2 is subject to previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, which may be affected (see Articles **S9** and **S11**).~~ For the use of the band 12.2-12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

Reasons:

1 For the suppression of the provisions relating to national or subregional systems, see EUR/13/138.

2 Europe has also addressed the issue raised at the CPM in relation to the possible replacement of Article S14/No. S9.21 to the FSS allocation in this band. Europe considers that there is a need, in order:

- to avoid undue constraints to the terrestrial services allocated in the bands in the three Regions;
- to avoid undue constraints on the development of the Plans in Regions 1 and 3;
- to limit the degree of inhomogeneity between different GSO FSS networks;
- to apply pfd limits to the operation of GSO FSS in Region 2 to ensure the protection of terrestrial services in the three Regions. For this purpose, the pfd limits currently in force in the adjacent band (12.2-12.5 GHz) are considered to be appropriate and are therefore proposed for this purpose. In doing so, the reference to footnote 7 in this particular part of Table S21-4 is no longer required, since this footnote refers to the applicability of limits in ITU-R Recommendations.

MOD EUR/13/378

TABLE **S21-4** *(continued)*

PART 7E

PP-98 Resolutions

PART 7E2

PP-98 Resolution 86 - Scope of S5.43

Add the following section at the end of Part 7 E2 of the European common proposals.

3 Scope of No. S5.43

3.1 Introduction

Past WRCs have introduced in Article S5 of the Radio Regulations footnotes to the effect that stations in a particular service “shall not cause harmful interference to” or “shall not claim protection from” stations in (an)other service(s) allocated in the table. No. S5.43 and its associated Rule of Procedure may be understood as establishing a general linkage between an allocation subject to not causing harmful interference and an allocation which cannot claim protection from the other services allocated in the table of Article S5. Such a general linkage appears to be in contradiction with most of the footnotes which may be considered within the scope of No. S5.43. After detailed review of this issue, this contribution proposes the modification of this provision. This proposal is made in the framework of the WRC-2000 agenda item relating to Resolution 86 of the Plenipotentiary Conference (Minneapolis, 1998), since in most cases, the relevant footnotes relate to space services.

It is also proposed that WRC-2000 adopt a resolution requesting ITU-R to study the sharing situations in the footnotes identified in this contribution and that WRC-03 reviews these situations with a view to clarify the regulatory situations in the corresponding bands and suppressing S5.43. The RRB should also be requested to revise its RoP on the basis of the decisions of the Conference on this issue.

As a general conclusion, future conferences should avoid adding footnotes in Article S5 which may fall in the scope of S5.43, since such decisions do not provide for satisfactory protection of incumbent services, nor provide any status to new services.

3.2 Framework

S1.169 of the Radio Regulations defines *harmful interference* as follows:

> "*Interference* which endangers the functioning of a *radionavigation service* or of other *safety services* or seriously degrades, obstructs, or repeatedly interrupts a *radiocommunication service* operating in accordance with Radio Regulations (CS)."

The main purpose of the Radio Regulations is to define allocations and procedures which preclude the occurrence of harmful interference between services. This fundamental principle is one of the first provisions of the Radio Regulations and echoes No. 197 of the Constitution:

S0.4 All stations, whatever their purpose, must be established and operated in such a manner as not to cause harmful interference to the radio services or communications of other Members or of recognized operating agencies, or of other duly authorized operating agencies which carry on a radio service, and which operate in accordance with the provisions of these Regulations (No. 197 of the Constitution).

Under this general principle, Article S5 specifies two categories of radiocommunication services (primary and secondary), with the following definition of a secondary service:

S5.28 3) Stations of a secondary service:

S5.29 *a)* shall not cause harmful interference to stations of primary services to which frequencies are already assigned or to which frequencies may be assigned at a later date;

S5.30 *b)* cannot claim protection from harmful interference from stations of a primary service to which frequencies are already assigned or may be assigned at a later date;

S5.31 *c)* can claim protection, however, from harmful interference from stations of the same or other secondary service(s) to which frequencies may be assigned at a later date.

No. S5.43 appears as creating a third category of services, lower than secondary, but higher than under S4.4, by using the following wording:

S5.43 1) Where it is indicated in these Regulations that a service may operate in a specific frequency band subject to not causing harmful interference, this means also that this service cannot claim protection from harmful interference caused by other services to which the band is allocated under Chapter **SII** of these Regulations.

The current RRB Rule of Procedure on this provision recognizes this lower status and extends it to the cases of allocations made without the right to claim protection. This Rule of Procedure therefore introduces a general linkage between an allocation subject to not causing harmful interference and an allocation which cannot claim protection, even when the allocation is made subject to not causing harmful interference into only one of the other services allocated in Article S5 in the same frequency band.

Such a general linkage is in contradiction with most of the footnotes which may be considered within the scope of No. S5.43. A careful analysis of these footnotes shows that in most cases, it appears that was not the intention of the Conference which decided the inclusion of these footnotes in the RR to make the corresponding allocation less than secondary, or even to make it secondary with respect to more than one service.

The footnotes of Article S5 which may be within the scope of S5.43 or its RoP may be grouped in seven categories:

- Category 1 (may operate… subject to not causing harmful interference to...) (this is the exact wording of S5.43);

- Category 2 (may be used under the condition not to cause…);
- Category 3 (shall not cause…);
- Category 4 (shall ensure/take all practicable steps not to cause harmful interference is caused…);
- Category 5 (shall not cause harmful interference or claim protection…);
- Category 6 (shall not cause harmful interference or constrain the development/use …);
- Category 7 (shall not claim protection from/constrain the development of...).

Category	Footnote in Article S5 (S5.xx)
1	243, 282, 289, 291, 553, 558, 559
2	60, 73, 97, 106, 128, 129, 136, 137, 143, 146, 147, 151, 254, 475

3.3 Proposals

EUR/13/379

It is proposed that the following principles be followed in considering the applicability of S5.43:

a) When a conference specified (a) particular service(s) to which the allocation identified shall not cause harmful interference, S5.43 can only be understood as implying that an administration using this allocation cannot claim protection from this (these) particular service(s).

b) When WRCs have specified that a given service “shall not causing harmful interference to and not claim protection from (or constrain the development of)” a particular service (e.g. S5.164, S5.221, S5.233, S5.235), the generalized interpretation of section 2 of the RoP on S5.43 (i.e. status less than all other services) can by no means be applied.

c) When it is specified in a footnote of Article S5 (e.g. S5.376A) that a service shall not cause harmful interference into a passive service like radio astronomy, it can by no means be interpreted as implying that S5.43 applies.

d) When the obligation not to cause harmful interference is into a service only allocated in certain countries, it can by no means be interpreted as implying that S5.43 applies.

On the basis of these principles, it can be seen that none of the above footnotes would be affected by the following alternative drafting of S5.43.

MOD EUR/13/380

S5.43 1) Where it is indicated in these Regulations that a service or stations in a service may operate in a specific frequency band subject to not causing harmful interference to another specified service or to other services allocated in this frequency band, this means also that the former~~this~~ service or stations cannot claim protection from harmful interferencecaused by the latter ~~other~~ service(s) or stations.~~to which the band is allocated under Chapter **SII** of these Regulations.~~

3.4 Conclusion

The discrepancies identified in this contribution between S5.43 and many of the footnotes in Article S5 need to be corrected by WRC-2000. Initial proposals are made to this effect. However, it is also proposed that WRC-2000 adopt a resolution requesting ITU-R to study the sharing situations in the footnotes identified in this contribution and that WRC-03 reviews these situations with a view to clarify the regulatory situations in the corresponding bands and suppressing S5.43. The RRB should also be requested to revise its RoP on the basis of the decisions of the Conference on this issue.

Recent conferences have increasingly used in the footnotes of Article S5, a sentence which is a principle that has guided their decision (“shall not cause harmful interference”). In doing so, it means that the incumbent services (which are “protected” from harmful interference by these few words appearing in a footnote of Article S5), are in fact only protected by the application of Section VI of Article S15, which is the procedure to follow in case harmful interference occurs in practice. Since ITU-R has not defined any technical criteria to define such a level, this means that the whole burden of sharing is left to the administrations without any upfront examination by the Bureau or any guideline for the administration that may cause the interference.

Allocations subject to “not causing harmful interference” therefore do not provide for satisfactory protection of incumbent services, nor provide any status to new services, unless they are coupled with clearly defined criteria. If the current trend was to continue, it would mean that in the long term, the whole Radio Regulations may be reduced to S0.4. It is therefore suggested that a preferable way of making new allocations would be to clarify the obligations of each service and to specify the sharing criteria by appropriate power limitations, whenever possible, and to request ITU-R to conduct the relevant studies necessary to achieve this objective.

PART 7F

Agenda items 7.1 and PP-98 Resolution 86

Report of the Director BR - Rules of Procedure - S11.44
Resolution 86 (PP-98) - S11.44

Add the following Part 7F in the European common proposals.

1 Background

The above administrations have noted a problem in the application of S11.44 and the Boards Rules of Procedure for the application of this provision.

The second part of paragraph 7.1 of the Rules deals with the case in which the network has not reached the stage where its frequencies can be notified. As is well known, coordination is becoming a very complex and long drawn out process and this is complicated when there are delays by the BR in the publication of the coordination requests. It is not unusual for the coordination process to take a number of years and therefore, it may not be possible to notify before the 5-year period even though the frequencies may been brought into use. No S11.32A provides for the notification of frequencies when the coordination **could not be successfully completed** by requesting BR to do an examination for the probability of harmful interference. In many cases the coordination process has not failed, it just takes more time to complete, and administrations are reluctant to use the provisions of S11.32A, while there is still a chance to complete the bilateral coordination successfully. Another approach to this problem has been to suggest that the technical examination under S11.32A could be deleted and the frequencies could be entered in the MIFR under a revised S11.41. The proposals in this document assume that there is no change to S11.32A.

The last phrase of the 2nd last sentence for rule for paragraph 7.1 ("provided that administration request to the Bureau to apply Nos. **S11.32A** and/or **S11.41**") would seem to indicate that the frequencies will be cancelled at the end of the 5-year period unless the BR is requested to intervene-even if the concerned administrations are continuing to try to resolve the problems. Considering that the intent of the Regulations is to foster the resolution of potential problems by the administrations concerned, the last phrase of this sentence seems to be contrary to the spirit of the Regulations.

For real networks that are in operation and can submit or have submitted the Resolution 49 data, it is necessary to have a regulatory environment that recognizes the real problems and time necessary to resolve all coordination issues. On the one hand it is desirable for administrations to arrive at their own coordination agreements, however, it is necessary that the regulatory status of networks not be left uncertain forever. On the other hand, it is necessary that with the long coordination times (including the publications delays by BR), we find a mechanism of not penalizing “real networks”, therefore, it is suggested that for systems that have been brought into use with the 5-year period, a further period of 2 years be allowed to complete the coordination. This would have the effect of providing a total period of 7 years (including the publication delays by BR) for all networks to complete the coordination. For networks that have received an extension of 2 years under S11.44 they already have 7 years to complete the coordination and to notify the assignments to the BR.

A proposed change to the Rules of Procedure was submitted to the 19th meeting of the RRB and this was not accepted by the RRB, consequently in accordance with No. S13.14 it is proposed to modify No. S11.44 to clarify its application in this type of case.

2 Proposals

MOD EUR/13/381

S11.44 The notified date[1] of bringing into use of any assignment to a space station of a satellite network shall be no later than five years following the date of receipt by the Bureau of the relevant information under No. **S9.1**. The notified date of bringing into use may be extended at the request of the notifying administration by not more than two years, only under the conditions specified under Nos. **S11.44B** to **S11.44I**. Any frequency assignment not brought into use within the required period shall be cancelled by the Bureau after having informed the administration at least three months before the expiry of this period.

ADD EUR/13/382

16 **S11.44.1** [1)]In the case of satellite frequencies that are brought into use prior to the completion of the coordination process and for which the Resolution **49 (WRC-97)** data has been submitted to the Bureau, the network frequencies shall continue to be taken into consideration for a maximum period of 7 years from the date of receipt of the relevant information under No. **S9.1**. If the frequencies have not been notified by the end of this 7-year period, the relevant frequencies shall be cancelled by the Bureau.

PLENARY MEETING

ANNEX 1 TO PART 7C OF THE EUROPEAN COMMON PROPOSALS

(APPENDIX S7)

In EUR/13/269, it is proposed to replace the entire text of Appendix S7 by the text attached in Annex 1 of PART 7C of the European Common Proposals. This Annex contains the essential regulatory text derived from Recommendation ITU-R SM.[Doc. 1/1004], together with the modified material from Appendix S5 relating to predetermined coordination distances, as included in Annex 1 of Chapter 7 of the CPM Report. The changes from Document 1/1004 are the following:

1 The deletion of:

– earth station sharing scenarios not covered by the provisions of the Radio Regulations;

– procedures not permitted under the provisions of the Radio Regulations;

– an optional method for determining the horizon gain of earth stations operating to non-geostationary space stations;

– examples and other non-essential texts.

2 The addition of predetermined coordination distances (relocated from Appendix S5).

3 The editorial restructuring of the document into the format used within the Radio Regulations.

APPENDIX S7

Methods for the determination of the coordination area around an earth station in frequency bands between 100 MHz and 105 GHz

1 Introduction

This Appendix addresses the determination of the coordination area (see No. S1.171) around a transmitting or receiving earth station, that is sharing spectrum in frequency bands between 100 MHz and 105 GHz with terrestrial radiocommunication services, or with earth stations operating in the opposite direction of transmission.

The coordination area represents the area surrounding an earth station sharing the same frequency band with terrestrial stations, or the area surrounding a transmitting earth station that is sharing the same bidirectionally allocated frequency band with receiving earth stations, within which the permissible level of interference may be exceeded and hence, coordination is required. The coordination area is determined on the basis of known characteristics for the coordinating earth station and on conservative assumptions for the propagation path and for the system parameters for the unknown terrestrial stations (see Tables 1 and 2 of Annex VII), or the unknown receiving earth stations (Table 3 of Annex VII), that are sharing the same frequency band.

1.1 Overview

This Appendix contains procedures and system parameters for calculating an earth station's coordination area, including predetermined distances.

The procedures allow the determination of a distance in all azimuthal directions around a transmitting or receiving earth station, beyond which the predicted path loss would be expected to exceed a specified value for all but a specified percentage of the time. This distance is called the coordination distance (see No. S1.173). When the coordination distance is determined for each azimuth around the coordinating earth station it defines a distance contour, called the coordination contour (see No. S1.172), that encloses the coordination area.

It is important to note that although the determination of the coordination area is based on technical criteria it represents a regulatory concept. Its purpose is to identify the area within which detailed evaluations of the interference potential need to be performed in order to determine whether the coordinating earth station or any of the terrestrial stations, or in the case of a bidirectional allocation any of the receiving earth stations that are sharing the same frequency band, will experience unacceptable levels of interference. Hence, the coordination area is not an exclusion zone within which the sharing of frequencies between the earth station and other terrestrial stations or earth stations is prohibited, but a means for determining the area within which more detailed calculations need to be performed. In most cases a more detailed analysis will show that sharing within the coordination area is possible since the procedure for the determination of the coordination area is based on unfavourable assumptions with regard to the interference potential.

For the determination of the coordination area, two separate cases may have to be considered:

– for the earth station when it is transmitting and hence capable of interfering with receiving terrestrial stations or earth stations;

– for the earth station when it is receiving and hence it may be the subject of interference from transmitting terrestrial stations.

Calculations are performed separately for great circle propagation mechanisms (propagation mode (1)) and, if required by the sharing scenario (see § 1.4), for scattering from hydrometeors (propagation mode (2)). The coordination contour is then determined using the greater distance predicted by the propagation mode (1) and propagation mode (2) calculations for each azimuth around the coordinating earth station. Separate coordination contours are produced for each sharing scenario. Guidance and examples of the construction of coordination contours, and their component propagation mode (1) and propagation mode (2) contours are provided in § 1.6.

To facilitate bilateral discussion (see No. S9.53 and S9.53.1) it can be useful to calculate additional contours, defining smaller areas, that are based on less conservative assumptions than those used for the calculation of the coordination contour.

1.2 Appendix structure

In this Appendix the general principles are separated from the detailed text on methods. The former is contained in the main body of this Appendix and the latter are contained in a series of annexes, enabling the user to select only those sections that are relevant for a specific sharing scenario.

Table 1 is provided to help the user to navigate through the Appendix and Annexes, it also indicates the relevant sections that need to be explored for a specific coordination case.

1.3 Basic concepts

Determination of the coordination area is based on the concept of the permissible interference power at the antenna terminals of a receiving terrestrial station or earth station. Hence, the attenuation required to limit the level of interference between a transmitting terrestrial station or earth station and a receiving terrestrial station or earth station to the permissible interference power for *p*% of the time is represented by the "minimum required loss". Where, the minimum required loss is the loss that needs to be equalled or exceeded by the predicted path loss for all but *p*% of the time*.

For propagation mode (1) the following equation applies:

$$L_b(p) = P_t + G_t + G_r - P_r(p) \qquad \text{dB} \tag{1}$$

where

- p: the maximum percentage of time for which the permissible interference power may be exceeded;
- $L_b(p)$: the propagation mode (1) minimum required loss (dB) for *p*% of the time; this value must be exceeded by the propagation mode (1) predicted path loss for all but *p*% of the time;
- P_t: the maximum available transmitting power level (dBW) in the reference bandwidth at the terminals of the antenna of a transmitting terrestrial station or earth station;
- $P_r(p)$: permissible interference power of an interfering emission (dBW) in the reference bandwidth to be exceeded for no more than *p*% of the time at the terminals of the antenna of a receiving terrestrial station or earth station that may be subject to interference, where the interfering emission originates from a single source;
- G_t: the gain (dB relative to isotropic) of the antenna of the transmitting terrestrial station or earth station. For a transmitting earth station, this is the antenna gain towards the physical horizon on a given azimuth; for a transmitting terrestrial station, the maximum main beam axis antenna gain is to be used;
- G_r: the gain (dB relative to isotropic) of the receiving antenna of the terrestrial or earth station that may be subject to interference. For a receiving earth station, this is the gain towards the physical horizon on a given azimuth; for a receiving terrestrial station, the maximum main beam axis antenna gain is to be used.

For propagation mode (2), a volume scattering process is involved and a modification of the above approach is necessary. Where the coordinating earth station antenna beam intersects a rain cell, a common volume may be formed with a terrestrial station beam or an earth station beam (operating in the opposite direction of transmission in bidirectionally allocated frequency bands). In the case of a terrestrial station, the assumptions are made that the terrestrial station beamwidth is relatively large in comparison with that of the coordinating earth station (terrestrial station gain values are given in Tables 1 and 2 of Annex VII) and that the terrestrial station is some distance from the common volume. The terrestrial station beam is therefore assumed to illuminate the whole rain cell, which is represented by a vertical cylinder filled with hydrometeors that give rise to isotropically

* When *p* is a small percentage of the time, in the range 0.001% to 1.0%, the interference is referred to as "short-term"; if *p* ≥ 20%, it is referred to as "long-term" (see § 1.5.3).

scattered signals. This scattering process may give rise to unwanted coupling between the coordinating earth station and terrestrial stations or earth stations operating in bidirectionally allocated frequency bands, via the common volume.

The earth station antenna gain and its beamwidth are inter-dependent. The size of the common volume, and the number of scattered signals arising within that volume, increases as the gain of the earth station antenna transmitting or receiving those signals decreases, the one effect compensating for the other. A term which approximates the full integral required to evaluate the volume scattering process within the earth station antenna beam is included in equation II-21. Therefore in the procedure for evaluation of interference that may arise from propagation mode (2) mechanisms a simplifying assumption can be made that the path loss is independent of the earth station antenna gain[1].

Hence for propagation mode (2), equation (1) reduces to:

$$L_x(p) = P_t + G_x - P_r(p) \qquad \text{dB} \tag{2}$$

where

$L_x(p)$: is the minimum loss required for propagation mode (2).

G_x: is the maximum antenna gain (dBi) assumed for the terrestrial station. Tables 1 and 2 of Annex VII give values of G_x for the various frequency bands.

To facilitate the calculation of propagation mode (2) auxiliary contours (see § 1.6.2.2) the calculation is further modified by placing the terrestrial network antenna gain G_x within the iterative loop for the propagation mode (2) required loss calculations[2].

Hence equation (2) further reduces to:

$$L(p) = P_t - P_r(p) \qquad \text{dB} \tag{3}$$

where

$L(p)$: the propagation mode (2) minimum required loss (dB) for p% of the time; this value must be exceeded by the propagation mode (2) predicted path loss for all but p% of the time.

For both modes of propagation, P_t and $P_r(p)$ are defined for the same radio-frequency bandwidth (the reference bandwidth). Further $L_b(p)$, $L(p)$ and $P_r(p)$ are defined for the same small percentage of the time, and that these values are set by the performance criteria of the receiving terrestrial, or receiving earth station, that may be subject to interference.

For an earth station operating to geostationary space stations, Annex III provides the numerical method for determining the minimum angle between the earth station antenna main beam axis and the physical horizon as a function of azimuth, and the corresponding antenna gain. In the case of a

---

[1] If the earth station antenna has a wide beamwidth, the method can still be used to determine the propagation mode (2) contour. However, the fact that the antenna beam may be wider than the rain cell and hence not actually fully filled with hydrometeors will mean that the interference potential may be slightly over-estimated.

[2] See equation II-21.

space station in a slightly inclined geostationary orbit, the minimum elevation angle and corresponding horizon gain will depend on the maximum inclination angle to be coordinated.

For an earth station operating to non-geostationary space stations, the antenna gain in the direction of the horizon of the earth station varies as a function of time and Annex IV provides the numerical methods for its determination.

For an earth station operating in a frequency band with a bidirectional allocation, the antenna gain to be used in determining the propagation mode (1) minimum required loss is calculated using the methods in Annex III, or Annex IV, as appropriate.

Determination of the coordination area requires the calculation of the predicted path loss and its comparison with the minimum required loss, for every azimuth around the coordinating earth station, where:

1) the predicted path loss, is dependent on several factors including the length and general geometry of the interfering path (e.g., antenna pointing, horizon elevation angle), antenna directivity, radio climatic conditions, and the percentage of the time during which the predicted path loss is less than the minimum required loss; and

2) the minimum required loss is based on system and interference model considerations.

The required coordination distance is the distance at which these two losses are considered to be equal for the stated percentage of time.

In determining the coordination area the pertinent parameters of the coordinating earth station are known, but knowledge of the terrestrial stations or other earth stations sharing that frequency range is limited. Hence it is necessary to rely on assumed system parameters for the unknown terrestrial stations or the unknown receiving earth stations. Further, many aspects of the interference path between the coordinating earth station and the terrestrial stations or other earth stations (e.g. antenna geometry and directivity) are unknown.

The determination of the coordination area is based on unfavourable assumptions regarding system parameter values and interference path geometry. However, in certain circumstances, to assume that all the worst-case values will occur simultaneously is unrealistic, and leads to unnecessarily large values of minimum required loss. This could lead to unnecessarily large coordination areas. For propagation mode (1) detailed analyses, supported by extensive operational experience, have shown that the requirement for the propagation mode (1) minimum required loss can be reduced because of the very small probability that the worst case assumptions for system parameter values and interference path geometry will exist simultaneously. Therefore a correction is applied within the calculation for the propagation mode (1) predicted path loss in the appropriate sharing scenario to allow benefit to be derived from these mitigating effects. The application of this correction factor is described in more detail in § 4.4.

This correction applies to cases of coordination with the fixed service. It is frequency, distance and path dependent. It does not apply in the case of the coordination of an earth station with mobile stations, or with other earth stations operating in the opposite direction of transmission, nor in the case of propagation via hydrometeor scatter (propagation mode (2)).

A number of propagation models are used to cover the propagation mechanisms that exist in the full frequency range. These models predict the path loss as a monotonically increasing function of distance. Therefore, coordination distances are determined by calculating the path loss iteratively for an increasing distance until either the minimum required loss is achieved, or a maximum calculation distance limit is reached (see § 1.5.3).

The iteration method always starts at a defined value of minimum distance, d_{min} in km, and iteration is performed using a uniform step size (*s* km) for increasing the distance, a step size of 1 km is recommended.

1.4 Sharing scenarios

The following subsections describe the basic assumptions made for the various earth station sharing scenarios. These subsections need to be read in conjunction with the information contained in Table 1 and § 1.6 which contains guidance on the development of a coordination contour.

1.4.1 Earth stations operating to geostationary space stations

For an earth station operating to a space station in the geostationary orbit, the space station appears to be stationary with respect to the Earth. However variations in gravitational forces acting on the space station and limitations in positional control mean a geostationary space station's orbital parameters are not constant. Movement from the space station's nominal orbital position in an east/west direction (longitudinal tolerance) is limited within the Radio Regulations (see No. S22.6 to No. S22.18), but movement in the north/south direction (inclination excursion) is not specified.

Relaxation in the north/south station-keeping of a geostationary space station allows its orbit to become inclined with an inclination that increases gradually with time. Therefore the determination of the coordination area requires consideration of the range of movement of the earth station antenna. Although the direction of pointing of the earth station antenna may in practice vary with time, the earth station antenna may also be pointing in one direction for considerable periods of time. Hence the gain of the earth station antenna in the direction of the horizon is assumed to be constant. For an earth station operating to a space station in an orbit as described above, an assumption of constant horizon gain as the inclination angle increases may lead to a conservative estimation of the coordination area, the degree of conservatism increases with increasing inclination angle.

For an earth station operating to a geostationary space station the coordination area is determined using the procedures described in § 2.1.

1.4.2 Earth stations operating to non-geostationary space stations

Earth stations operating to a non-geostationary space station may use a directional or a non-directional antenna. Furthermore, earth stations using a directional antenna may track the orbital path of a non-geostationary space station.

While an earth station operating to a geostationary space station is assumed to have a constant antenna gain towards the horizon, for an earth station antenna that is tracking the orbital path of a non-geostationary space station, the antenna gain towards the horizon will vary with time. Therefore, it is necessary to estimate the variation of the antenna gain with time towards the horizon for each azimuth in order to determine the coordination area. The procedure is described in § 2.2.

For an earth station operating to a non-geostationary space station, the motion of a relatively high gain tracking antenna reduces the probability of interference due to propagation mode (2) mechanisms and hence the propagation mode (2) required distances will be relatively short. The minimum coordination distance d_{min} (see § 1.5.3) will provide adequate protection in these cases. The propagation mode (2) contour is therefore taken to be identical to a circle represented by the minimum coordination distance. Propagation mode (2) calculations are not required in these circumstances and the coordination area is determined using the propagation mode (1) procedure in § 2.2 only.

For an earth station operating to a non-geostationary space station using a non-directional antenna, a similar situation applies, and the low gain means that propagation mode (2) required distances will be less than the minimum coordination distance. Hence for the case of non-directional antenna the propagation mode (2) contour is also coincident with the circle represented by d_{min}, and the coordination area is determined using the propagation mode (1) procedures described in § 2.1.1, only.

For an earth station operating to a non-geostationary space station using a non-tracking directional antenna, the potential for interference arising from propagation mode (2) is identical to an earth station operating to a geostationary space station. Hence, for the case of non-tracking directional antenna the coordination area is determined using both the propagation mode (1) and propagation mode (2) procedures described in § 2.1.

1.4.3 Earth stations operating to both geostationary and non-geostationary space stations

For earth stations that are sometimes intended to operate to geostationary space stations and at other times to non-geostationary space stations, separate coordination areas are determined for each type of operation. In such cases, the coordination area for the geostationary space station is determined using the procedures described in § 2.1 and, in addition, the coordination area for the non-geostationary space station is determined using the procedure described in § 2.2.

1.4.4 Earth stations operating in bidirectionally allocated frequency bands

For earth stations operating in some frequency bands there may be equal primary allocations to space services operating in both the Earth-to-space and space-to-Earth directions. In this case, where two earth stations are operating in opposite directions of transmission it is only necessary to establish the coordination area for the transmitting earth station, as receiving earth stations will automatically be taken into consideration. Hence, a receiving earth station operating in a bidirectionally allocated frequency band will only be involved in coordination with a transmitting earth station if it is located within the transmitting earth station's coordination area.

For a transmitting earth station operating to either geostationary or non-geostationary satellites in a bidirectionally allocated frequency band, the coordination area is determined using the procedures described in § 3.

1.4.5 Broadcasting-satellite service earth stations

For earth stations in the broadcasting-satellite service operating in the unplanned bands, the coordination area is determined by extending the periphery of the specified service area, within which the earth stations are operating, by the coordination distance which is based on a typical BSS earth station. In calculating the coordination distance no additional protection can be assumed to be available from the earth station horizon elevation angle, i.e. $A_h = 0$ dB in Annex I, for all azimuth angles around the earth station.

1.4.6 Mobile (except aeronautical mobile) earth stations

For a mobile (except aeronautical mobile) earth station, the coordination area is determined by extending the periphery of the specified service area, within which the mobile (except aeronautical mobile) earth stations are operating, by the coordination distance. The coordination distance may be represented by a predetermined coordination distance (see § 4 of Annex VII), or it may be calculated. In calculating the coordination distance no additional protection can be assumed to be available from the earth station horizon elevation angle, i.e. $A_h = 0$ dB in Annex 1, for all azimuth angles around the earth station.

1.4.7 Aeronautical mobile earth stations

For aeronautical mobile earth stations the coordination area is determined by extending the periphery of the specified service area, within which the aeronautical mobile earth station operates, by an appropriate predetermined coordination (see § 4 of Annex VII) distance for the respective services.

1.5 Propagation model concepts

For each mode of propagation, according to the requirements of the specific sharing scenario (see § 1.4) it is necessary to determine the predicted path loss. The determination of this predicted path loss is based on a number of propagation mechanisms.

Interference may arise through a range of propagation mechanisms whose individual dominance depends on climate, radio frequency, time percentage of interest, distance and path topography. At any one point in time, one or more mechanisms may be present. The propagation mechanisms that are considered within this Appendix in the determination of the interference potential are as follows:

– *Diffraction*: In as far as it relates to diffraction losses occurring over the earth station's local physical horizon. This effect is referred to below as "site shielding". The remainder of the path along each radial is considered to be flat and therefore free of additional diffraction losses.

– *Tropospheric scatter*: This mechanism defines the "background" interference level for paths longer than about 100 km beyond which the diffraction field becomes very weak.

– *Surface ducting*: This is the most important short-term interference mechanism over water and in flat coastal land areas, and can give rise to high signal levels over longer distances, sometimes more than 500 km. Such signals can exceed the equivalent "free-space" level under certain conditions.

– *Elevated layer reflection and refraction*: The treatment of reflection and/or refraction from layers at heights up to a few hundred metres is an important mechanism that enables signals to by-pass any diffraction losses due to the underlying terrain under favourable path geometry situations. Again the impact can be significant over long distances.

– *Hydrometeor scatter*: Hydrometeor scatter can be a potential source of interference between terrestrial link transmitters and earth stations because it may act isotropically, and can therefore have an impact irrespective of whether the common volume is on or off the great-circle interference path between the coordinating earth station and terrestrial stations, or receiving earth stations operating in bidirectionally allocated frequency bands.

In this Appendix propagation phenomena are classified into two modes as follows:

– *Propagation mode (1)*: propagation phenomena in clear air, (tropospheric scatter, ducting, layer reflection/refraction, gaseous absorption and site shielding). These phenomena are confined to propagation along the great-circle path;

– *Propagation mode (2)*: hydrometeor scatter.

1.5.1 Propagation mode (1)

For the determination of the propagation mode (1) required distances, the applicable frequency range has been divided into three parts:

– For VHF/UHF frequencies between 100 MHz and 790 MHz and for time percentages from 1% to 50% of an average year.

– From 790 MHz to 60 GHz and for time percentages from 0.001% to 50% of an average year.

– From 60 GHz to 105 GHz and for time percentages from 0.001% to 50% of an average year.

The variation in predicted path loss due to the horizon elevation angle around an earth station is calculated by the method described in § 1 of Annex I using the horizon elevation angles and distances along different radials from the earth station. For all frequencies between 100 MHz and 105.0 GHz the attenuation arising from the horizon characteristics is included in the value of propagation mode (1) predicted path loss, unless its use is specifically prohibited for a particular sharing scenario (see § 1.4.5, § 1.4.6, § 1.4 and § 1.4.9).

In the determination of the propagation mode (1) required distance, the world is divided into four basic radio-climatic zones. These zones are defined as follows.

– Zone A1: coastal land, i.e. land adjacent to a Zone B or a Zone C area (see below), up to an altitude of 100 m relative to mean sea or water level, but limited to a maximum distance of 50 km from the nearest Zone B or Zone C area; in the absence of precise information on the 100 m contour, an approximation (e.g. 300 feet) may be used. Large inland areas of at least 7 800 km^2 which contain many small lakes, or a river network, comprising more than 50% water, and where more than 90% of the land is less than 100 m above the mean water level may be included in Zone A1*.

– Zone A2: all land, other than coastal land as defined in Zone A1 above.

– Zone B: “cold” seas, oceans and large bodies of inland water situated at latitudes above 30^o, with the exception of the Mediterranean Sea and the Black Sea. A “large” body of inland water is defined, for the administrative purpose of coordination, as one having an area of at least 7 800 km^2, but excluding the area of rivers. Islands within such bodies of water are to be included as water within the calculation of this area if they have elevations lower than 100 m above the mean water level for more than 90% of their area. Islands that do not meet these criteria should be classified as land for the purposes of calculating the area of the water.

– Zone C: “warm” seas, oceans and large bodies of inland water situated at latitudes below 30^o, as well as the Mediterranean Sea and the Black Sea.

1.5.2 Propagation mode (2)

For the determination of the propagation mode (2) required distance, interference arising from hydrometeor scatter can be ignored at frequencies below 1 000 MHz and above 40.5 GHz outside the minimum coordination distance (see § 1.5.3.1). Below 1 000 MHz the level of the scattered signal is very low and above 40.5 GHz, although significant scattering occurs, the scattered signal is then highly attenuated on the path from the scatter volume to the receiving terrestrial station or earth station. Site shielding is not relevant to propagation mode (2) mechanisms as the interference path is via the main beam of the coordinating earth station antenna.

* These additional areas may be declared as coastal Zone A1 areas by Administrations for inclusion in the ITU Digital World Map (IDWM).

1.5.3 Distance limits

The effect of interference on terrestrial and space systems often needs to be assessed by considering long and short term interference criteria. These criteria are generally represented by a permissible interference power not to be exceeded for more than a specified percentage of time.

The long-term criterion (typically associated with percentages of time ≥ 20%) protects the error performance objective (for digital systems) or noise performance objective (for analogue systems) objectives to meet specified long-term interference criteria. This criterion will generally represent a low level of interference and hence require a high degree of isolation between the coordinating earth station and terrestrial stations, or receiving earth stations operating in bidirectionally allocated bands.

The short-term criterion is a higher level of interference, typically associated with time percentages in the range 0.001% to 1% of time, which will either make the interfered-with system unavailable, or cause its specified short-term interference objectives (error rate or noise) to be exceeded.

This Appendix addresses only the protection of the short-term criterion. There is therefore an implicit assumption that if the short-term criterion is satisfied, then any associated long-term criteria will also be satisfied. This assumption may not remain valid at short distances because additional propagation effects (diffraction, building/terrain scattering etc.) requiring a more detailed analysis become significant. A minimum coordination distance is therefore needed to avoid this difficulty. This minimum coordination distance is always the lowest value of coordination distance used. At distances equal to or greater than the minimum coordination distance, it can be assumed that interference due to continuous (long-term) propagation effects will not exceed levels permitted by the long-term criteria.

In addition to the minimum coordination distance, it is also necessary to set an upper limit to the calculation distance. Hence the coordination distance, on any azimuth, must lie within the range between the minimum coordination distance and the maximum calculation distance.

1.5.3.1 Minimum coordination distance

For reasons stated in § 1.5.3 it is necessary to set a lower limit to the coordination distance (d_{min}). The iterative calculation of the coordination distance starts at this specified minimum distance and this distance varies according to radio-meteorological factors and the frequency band, (see § 4.2). The same minimum coordination distance applies to both propagation mode (1) and propagation mode (2) calculations.

1.5.3.2 Maximum calculation distance

Maximum calculation distances are required for propagation modes (1) and (2). In the case of mode (1) this distance corresponds to the maximum coordination distance, d_{max1}, given in § 4.3 for each of the four radioclimatic Zones. The propagation mode (1) maximum calculation distance is therefore dependent on the mixture of radioclimatic Zones in the propagation path. This dependency is described in § 4.3.

The maximum calculation distance for propagation mode (2) is given in § 2 of Annex II.

1.6 The coordination contour: concepts and construction

The coordination distance, determined for each azimuth around the coordinating earth station, defines the coordination contour that encloses the coordination area. The coordination distance lies within the range defined by the minimum coordination distance and the maximum calculation distance.

In this Appendix the procedures determine the distance at which the minimum required loss is equal to the predicted path loss. In addition some procedures[3] require that, for any azimuth, the greater of the distances determined for propagation mode (1) and propagation mode (2) is the distance to be used in determining the coordination contour. In both these cases, the distance at which the minimum required loss is equal to the predicted path loss may or may not be within the range of valid values that define the limits for the coordination distance. Hence the distance determined from the application of all the procedures is referred to as the required distance.

The coordination area is determined by one of the following methods:

– calculating, in all directions of azimuth from the earth station, the coordination distances and then drawing to scale on an appropriate map the coordination contour; or

– extending the service area in all directions by the calculated coordination distance(s); or

– for some services and frequency bands extending the service area in all directions by a predetermined coordination distance.

Where a coordination contour includes the potential interference effects arising from both propagation mode (1) and propagation mode (2), the required distance used for any azimuth is the greater of the propagation mode (1) and propagation mode (2) required distances.

The sharing scenarios and the various procedures contained in this Appendix are based on different assumptions. Hence the coordination area developed for one sharing scenario is likely to be based on different sharing considerations, interference paths and operational constraints than the coordination area developed under a different sharing scenario. Separate coordination areas are therefore required for each sharing scenario described in § 1.4. and each coordination area is specific to the radiocommunication services covered by the sharing scenario under which it was developed. Further, the coordination area developed for one sharing scenario cannot be used to determine the extent of any impact on the radiocommunication services covered by a different sharing scenario. Thus a coordinating earth station operating in a bidirectionally allocated frequency band and also sharing with terrestrial stations will have two separate coordination areas:

– one coordination area for determining those administrations with terrestrial services that may be affected by the operation of the coordinating earth station; and

– one coordination area for determining those administrations with receiving earth stations that may be affected by the operation of the coordinating (transmitting) earth station.

This means that the establishment of the coordination area for an earth station will generally require the determination of several individual coordination areas, each drawn on a separate map.

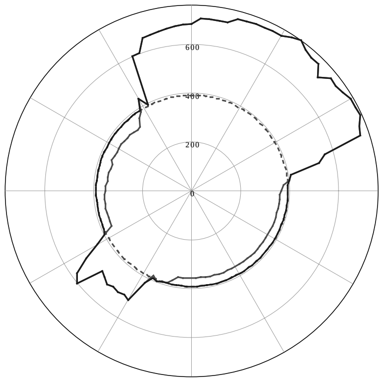
In addition separate coordination contours are produced if the earth station both transmits and receives in bands shared with terrestrial services. However, for earth stations in bidirectionally allocated frequency bands, the coordination contours with respect to other earth stations are only produced for a transmitting earth station (see § 1.4.4).

An example of the coordination area for each of the sharing scenarios in § 1.4 is provided in Figure 1. It will be noticed that for some of the sharing scenarios there is a commonality to the construction of the coordination contour (shown by a solid line) that encompasses each coordination area. For those sharing scenarios where both propagation mode (1) and propagation mode (2)

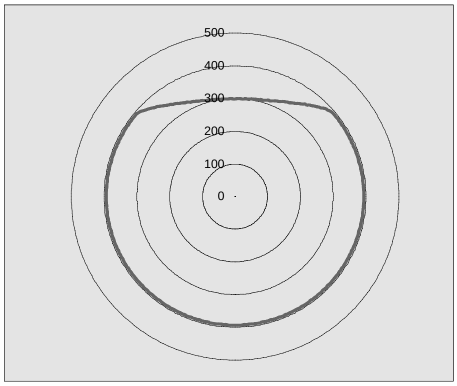
---

[3] The same procedures are also used to develop supplementary and auxiliary contours (see § 1.6.1 and § 1.6.2).

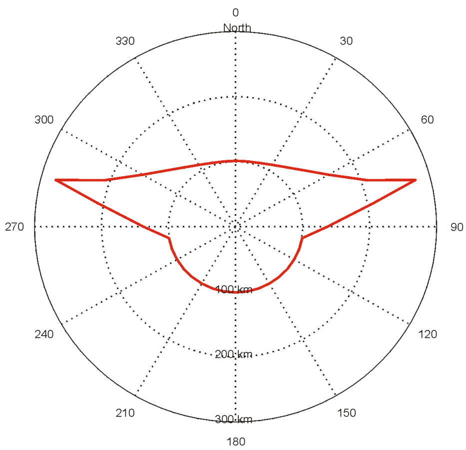
interference paths need to be taken into consideration, the parts of the propagation mode (1) contour and that part of the propagation mode (2) contour located within the overall coordination contour may be drawn using dashed lines.



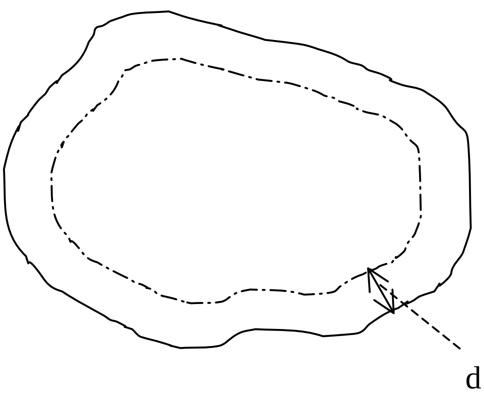
The coordination contour is an example of an earth station operating to a GSO space station in § 1.4.1 and § 1.4.3. The coordination contour is marked by the outer line and is comprised of a propagation mode (1) contour and a circular propagation mode (2) contour. The propagation mode (1) contour could also be an example of an earth station with a non-tracking directional antenna operating to a non-GSO space station in § 1.4.2.



The coordination contour is an example of an earth station with a tracking antenna operating to a non-GSO space station in § 1.4.2 and § 1.4.3.



The coordination contour is an example of an earth station operating in bidirectionally allocated frequency bands in § 1.4.4. The coordination contour has been developed from a propagation mode (1) contour for a coordinating earth station operating to a non-GSO space station with respect to unknown earth stations operating to GSO space stations. For a propagation mode (2) contour for the GSO-GSO case see Annex V.



The coordination contour is an example of an earth station operating in a specified service area in § 1.4.5, § 1.4.6, § 1.4.7. The coordination contour is marked by the solid outer line and the specified service area by the broken inner line. The coordination distance, d, may be a constant value, or vary with azimuth, depending on the sharing scenario and the type of radiocommunication service.

FIGURE 1

Examples of coordination contours for the sharing scenarios listed in § 1.4

In addition to the coordination contour, supplementary contours (see No. S9.53.1) and auxiliary contours (see § 1.6.1 and § 1.6.2) may be drawn to facilitate more detailed sharing discussions. Supplementary contours are based on the coordinating earth station sharing frequency bands with other radiocommunication services, or other types of radio systems in the same service, that have less onerous sharing criteria than the radio system used for developing the coordination area. These supplementary contours may be developed by the same method used to determine the coordination contour, or by other methods as agreed on a bilateral basis between administrations. Auxiliary contours are based on less conservative assumptions, with regard to the interference path and operational constraints, for the unknown terrestrial stations, or earth stations. Auxiliary contours are developed separately for propagation mode (1) and propagation mode (2) interference paths. In this context, the contours from which the coordination contour was developed are called main contours, and the auxiliary contours for propagation mode (1) and propagation mode (2) are referenced to the appropriate main contour. The variations in the assumptions used for developing auxiliary contours to the propagation mode (1) contour, or the propagation mode (2) contour, can also be applied to supplementary contours. Hence, auxiliary contours may be drawn for both a main, or a supplementary, contour.

Supplementary contours are always drawn on a separate map as they apply to other types of radio system within the same radiocommunication service, or to radio systems in different radiocommunication services. However, as auxiliary contours apply to variations in the assumptions used in developing the main, or supplementary, contour they are always drawn on the same map that contains the corresponding main, or supplementary, contour.

While the use of supplementary or auxiliary contours allows less conservative assumptions with regard to the interference path and operational constraints to be taken into consideration, earth stations may transmit or receive a variety of classes of emissions. Hence, the earth station parameters to be used in the determination of the coordination contour, and any supplementary or auxiliary contours, are those which lead to the greatest distances for each earth station antenna beam and each allocated frequency band which the coordinating earth station shares with other radiocommunication systems.

1.6.1 Supplementary contours

The coordination area is determined with respect to the type of terrestrial station (or in a frequency band with a bidirectional space allocation, an earth station operating in the opposite direction of transmission) that would yield the largest coordination distances. Therefore, in the case of terrestrial services: fixed stations using tropospheric scatter have been assumed to be operating in frequency bands that may typically be used by such radiocommunication systems; and fixed stations operating in line-of-sight configurations and using analogue modulation have been assumed to be operating in other frequency bands. However, other radiocommunication systems (e.g. other terrestrial stations), that have typically lower antenna gains, or otherwise less stringent system parameters, than those on which the coordination area is based, may also operate in the same frequency range. Therefore it is possible for the coordinating administration to identify a supplementary contour using either the methods in § 2 or § 3, where they are applicable, or other agreed methods. Subject to bilateral agreement between administrations, these supplementary contours can assume the role of the coordination contour for an alternative type of radio system in the same services, or another radiocommunication service.

When a supplementary contour is to be developed for other types of systems, for example digital fixed systems, the necessary system parameters may be found in one of the adjacent columns in Tables 1, 2 and 3 of Annex VII. If no suitable system parameters are available then the value of the permissible interference power ($P_r(p)$) may be calculated using equation (1) of § 2 in Annex VII.

In addition, supplementary contours may be prepared by the administration seeking coordination to define smaller areas, based on more detailed methods, for consideration when agreed bilaterally between the concerned administrations. These contours can be a useful aid to the rapid exclusion of terrestrial stations or earth stations from further consideration. Supplementary contours may be comprised of propagation mode (1) interference paths and, depending on the sharing scenario, propagation mode (2) interference paths. In addition, the propagation mode (1) element of a supplementary contour may, if appropriate for the radiocommunication service, utilise the same level of correction factor (see § 4.4) that was applied in the determination of the coordination contour. However, all parts of each supplementary contour must fall on or between the contour defined by the minimum coordination distance and the corresponding propagation mode (1) or propagation mode (2) main contour.

1.6.2 Auxiliary contours

Practical experience has shown that, in many cases, the separation distance required for the coordinating earth station, on any azimuth, can be substantially less than the coordination distance since the worst-case assumptions do not apply to every terrestrial station or earth station. There are two main mechanisms that contribute to the difference between the separation distance in this context and the coordination distance:

– the terrestrial station antenna gain (or e.i.r.p.), or receiving earth station antenna gain, in the direction of the coordinating earth station is less than that assumed in calculating the coordination contour;

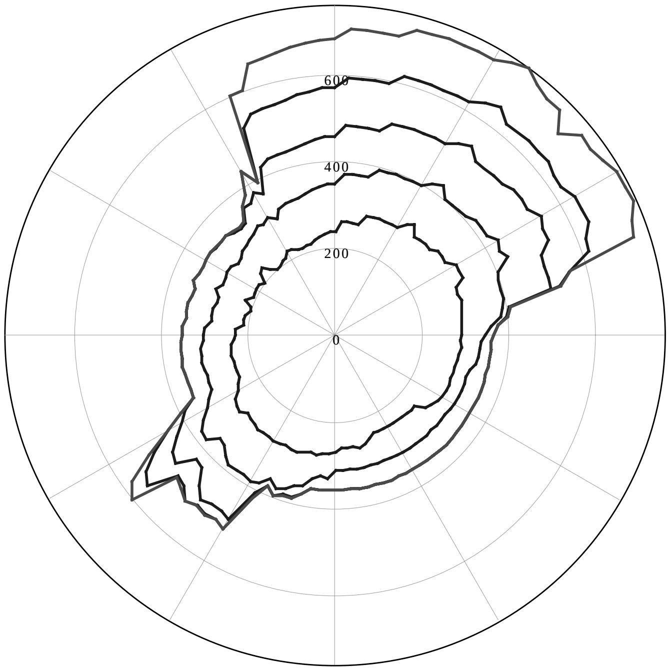
– appropriate allowance can be made, for example, for the effects of site shielding not included in the coordination distance calculations.

Auxiliary contours must use the same method as that used to determine the corresponding main or supplementary contour. In addition all parts of each auxiliary contour must fall on or between the contour defined by the minimum coordination distance and the corresponding main or supplementary contour. Auxiliary contours may assist in the elimination from detailed coordination of terrestrial stations or earth stations that are located in the coordination area and hence have been identified as potentially affected by the coordinating earth station. Any terrestrial station or earth station that lies outside an auxiliary contour and has an antenna gain towards the coordinating earth station that is less than the gain represented by the relevant auxiliary contour need not be considered further as a significant source, or subject, of interference.

1.6.2.1 Auxiliary contours for propagation mode (1)

Propagation mode (1) auxiliary contours are calculated with values for the propagation mode (1) minimum required loss, in equation (22) in § 4.4, that are progressively reduced by 5, 10, 15, 20 dB, etc., below the value assumed in Tables 1, 2 and 3 of Annex VII for the corresponding main or supplementary propagation mode (1) contour, until the minimum coordination distance is reached. Propagation mode (1) auxiliary contour distances are calculated without the correction factor (see § 4.4), and hence could be larger, on any azimuth, than the corresponding main, or supplementary, propagation mode (1) distance. To prevent this happening, in those cases where a correction factor applies to the main or supplementary contour, the maximum propagation mode (1) auxiliary contour distances on any azimuth is limited to the corresponding main or supplementary propagation mode (1) distance. In effect this means that the correction factor will limit the possible range of auxiliary contour values so that only those auxiliary contours with values greater than the applied correction factor will be shown within the main, or supplementary, contour (see Figure 2). For example, if the value of correction factor applicable to the propagation mode (1) main, or supplementary, contour is 10 dB, then the first auxiliary contour drawn would be for a reduction in minimum required loss of 5 dB and hence the auxiliary contour value would be –15 dB (by convention auxiliary contours are shown as negative quantities as they represent a reduction in the terrestrial, or receiving earth station, antenna gain, or the terrestrial station e.i.r.p).

Propagation mode (2) interference effects may still need to be considered even if propagation mode (1) interference effects have been eliminated from detailed coordination, as the propagation models are based on different interference mechanisms.



The propagation mode (1) auxiliary contours are shown for –10, –20, –30 and –40 dB adjustments in the minimum required loss.

FIGURE 2

Propagation mode (1) main contour and auxiliary contours

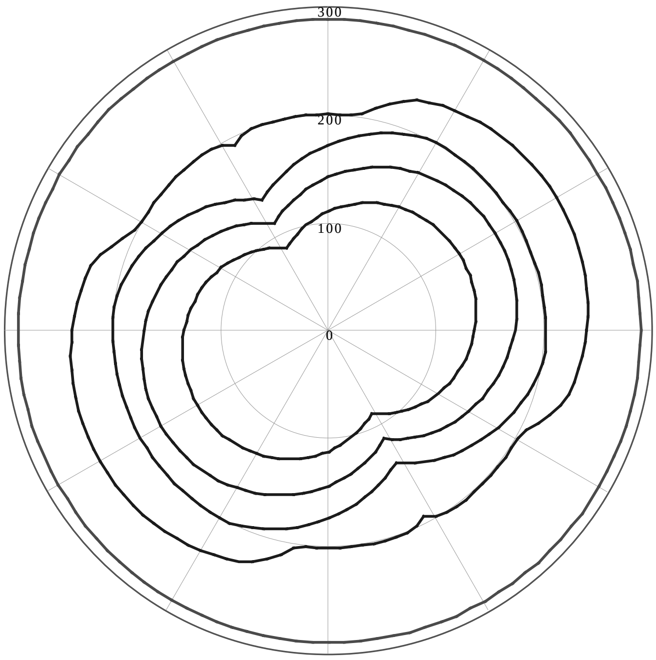
1.6.2.2 Auxiliary contours for propagation mode (2)

The propagation mode (2) contour around an earth station is calculated assuming the main beams of the coordinating earth station and the terrestrial station intersect exactly (see § 1.3). However, it is unlikely that these antenna main beams will intersect exactly. It is therefore possible to generate propagation mode (2) auxiliary contours that take account of any offset in the pointing of the terrestrial station antenna beam from the direction of the coordinating earth station. This offset would result in partial beam intersections and hence a reduced interference potential. These propagation mode (2) auxiliary contours are calculated according to the method described in Annex VI.

Propagation mode (2) auxiliary contours are not generated for different values of antenna gain or e.i.r.p. but for different values of beam avoidance angle. Hence, if there is a need to consider both a lower value of antenna gain, or e.i.r.p., for the terrestrial station and propagation mode (2) auxiliary contours, it is first essential to consider the impact of the reduction in antenna gain, or e.i.r.p., on the propagation mode (2) contour. This is achieved by generating a supplementary contour (see § 1.6.1) corresponding to the lower value of antenna gain or e.i.r.p. for the terrestrial station, which is drawn on a separate map. Auxiliary mode (2) contours can then be generated inside this propagation mode (2) supplementary contour for different values of the beam avoidance angle. Hence, propagation mode (2) auxiliary contours may be most frequently applied in conjunction with a supplementary contour rather than with the coordination contour.

The correction factor discussed in § 1.3 does not apply to propagation mode (2) interference paths and hence is also not applicable to propagation mode (2) auxiliary contours. In addition propagation mode (2) auxiliary contours cannot be developed for the bidirectional case.

Propagation mode (2) auxiliary contours are prepared for appropriate values of terrestrial station main beam avoidance angle (see Figure 3). When the antenna characteristics of the terrestrial stations are known, the appropriate antenna pattern[4] should be used when determining the propagation mode (2) auxiliary contours. If this not available, the reference antenna pattern given in § 3 of Annex VI may be used.



The propagation mode (2) auxiliary contours are shown for terrestrial station main beam avoidance angles of 2.0, 2.7, 3.2 and 4.0 degrees respectively.

FIGURE 3

Propagation mode (2) main contour and auxiliary contours

2 Determination of the earth station coordination area with respect to terrestrial stations

This section contains the procedures for determining the coordination area for the case of earth stations sharing frequency bands with terrestrial stations. These procedures cover the cases for earth

---

[4] The method requires the antenna pattern to be monotonic in terms of the reduction in gain either side of the main beam axis.

stations operating to space stations in the geostationary orbit, or in non-geostationary orbits, and are described in the following subsections.

For earth stations operating to space stations in non-geostationary orbits, consideration has to be given to the potential time-varying nature of the earth station's antenna gain towards the horizon.

2.1 The earth stations operate to geostationary space stations

For an earth station operating to a geostationary space station the value of G_t and G_r towards the horizon is considered to be constant with time. The percentage of time associated with L_b in equation (1) is the same as the time percentage, p, associated with $P_r(p)$. When determining the coordination area between a coordinating earth station operating to a geostationary space station and terrestrial systems, the coordination distance on any azimuth is the greater of the propagation mode (1) and propagation mode (2) required distances. The required distances for propagation mode (1) and propagation mode (2) are determined using the procedures described in § 2.1.1 and § 2.1.2 respectively, after taking into consideration the following discussion on station-keeping.

When the north/south station-keeping of a geostationary space station is relaxed, the orbit of the space station becomes inclined with an inclination that increases gradually with time. This movement of the space station from its nominal position may require small corresponding adjustments in the elevation angle of the earth station antenna beam. Hence, to avoid considering the time variation in antenna gain in the direction of the horizon, the coordination area of an earth station operating to a space station in a slightly inclined geostationary orbit is determined for the minimum angle of elevation and the associated azimuth at which the space station is visible to the earth station (see Annex III).

2.1.1 Determination of the coordinating earth station's propagation mode (1) contour

Determination of the propagation mode (1) contour is based on great circle propagation mechanisms and it is assumed, for the interference path, that all the terrestrial stations are pointing directly at the coordinating earth station's location. The required distance, on each azimuth, for propagation mode (1) is that distance which will result in a value of propagation mode (1) predicted path loss that is equal to the propagation mode (1) minimum required loss, $L_b(p)$ dB, as defined in § 1.3.

$$L_b(p) = P_t + G_e + G_x - P_r(p) \qquad \text{dB} \qquad (4)$$

where

- P_t: and $P_r(p)$ are as defined in § 1.3;
- G_e: the gain of the coordinating earth station antenna (dBi) towards the horizon at the horizon elevation angle and azimuth under consideration;
- G_x: the maximum antenna gain (dBi) assumed for the terrestrial station. Tables 1 and 2 of Annex VII give values for G_x for the various frequency bands.

The propagation mode (1) required distance is determined using the procedures described in § 4, and the detailed methods in Annex I. Specific guidance relevant to the application of the procedures is provided in § 4.4.

2.1.2 Determination of the coordinating earth station's propagation mode (2) contour

The required distance for hydrometeor scatter is that distance that will result in a propagation mode (2) predicted path loss equal to the propagation mode (2) minimum required loss L (p), as defined in equation (3). This propagation mode (2) required distance is determined using the guidance in § 5, and the detailed methods in Annex II.

For an earth station operating to a geostationary space station having a slightly inclined orbit, the rain-scatter coordination contour for each of the satellite's two most extreme orbit positions are determined individually, using the relevant elevation angles and their associated azimuths to the satellite. The rain scatter area is the total area contained within the two resulting overlapping coordination contours.

2.2 The earth stations operate to non-geostationary space stations

For earth stations that operate to non-geostationary space stations and track the space station, the antenna gain in the direction of the horizon on any azimuth varies with time.

The method used provides ease of implementation since it is not dependent on the availability of the distribution of the values for the horizon gain of the earth station antenna.

In the case of a receiving earth station, the permissible interference power $P_r(p)$ is specified with respect to the actual percentage of time the receiver is in operation, rather than the total elapsed time. Thus, the percentage of time p is specified for all the operational time that the receiving earth station is expected to spend in reception from non-geostationary space stations, but excludes any reception time involving geostationary space stations.

In considering the horizon gain of the antenna for either a transmitting or a receiving earth station, only the horizon gain values during the operational time are to be considered. Thus, there may be periods, or percentages, of time for which no horizon gain is specified. This presents no problem in the implementation of this method, and it is consistent with the permissible interference power for the unknown receiving stations specified in Table 1 of Annex VII and with the permissible interference powers for receiving earth stations, as discussed in the preceding paragraph, in Table 2 of Annex VII.

The horizon antenna gain may be determined using Annex IV. Reference or measured antenna radiation patterns may be used as described in Annex III.

The method uses fixed values of antenna gain based on the maximum assumed variation in horizon antenna gain on each azimuth under consideration. The values of horizon antenna gain defined below are used for each azimuth when applying equation (4) to determine the propagation mode (1) required distances:

$$\begin{array}{lll} G_e = G_{max} & \text{for} & (G_{max} - G_{min}) \leq 20\,\text{dB} \\ G_e = G_{min} + 20 & \text{for} & 20\,\text{dB} < (G_{max} - G_{min}) < 30\,\text{dB} \\ G_e = G_{max} - 10 & \text{for} & (G_{max} - G_{min}) \geq 30\,\text{dB} \end{array} \tag{5}$$

where

G_e: the gain of the coordinating earth station antenna (dBi) towards the horizon at the horizon elevation angle and azimuth under consideration in equation (4);

G_{max}, G_{min}: maximum and minimum values of the horizon antenna gain (dBi), respectively, on the azimuth under consideration.

The maximum and minimum values of the horizon antenna gain, on the azimuth under consideration, are derived from the antenna pattern and the maximum and minimum angular separation of the antenna main beam axis from the direction of the physical horizon at the azimuth under consideration.

Where a single value of minimum elevation angle for the main beam axis of the earth station antenna is specified for all azimuths, the minimum and maximum values of horizon gain can be determined, for each azimuth under consideration, from the antenna pattern and the horizon elevation angle at that azimuth. The plot of the horizon elevation angle against azimuth is called the horizon profile of the earth station.

Additional constraints maybe included in the determination of the maximum and minimum values of the horizon antenna gain where an earth station is operating to a constellation of non-geostationary satellites at a latitude for which no satellite is visible at the earth station's specified minimum elevation angle over a range of azimuth angles. Over this range of azimuth angles, the minimum elevation angle of the earth station antenna main beam axis is given by the minimum elevation angle at which any satellite of the constellation is visible at that azimuth. The azimuthal dependence of this minimum satellite visibility elevation angle may be determined from consideration of the orbital altitude and inclination of the satellites in the constellation, without recourse to simulation, using the procedure in § 1.1 of Annex IV. In this case, the horizon gain to be used in the method depends on the profile of the composite minimum elevation angle. This minimum composite elevation angle at any azimuth is the greater of the minimum satellite visibility elevation angle, at the azimuth under consideration, and the specified minimum elevation angle for the earth station which is independent of the azimuth.

Thus, at each azimuth under consideration, the maximum horizon antenna gain will be determined from the minimum value of the angular separation from the earth station horizon profile at this azimuth to the profile of the minimum composite elevation angle. Similarly, the minimum horizon antenna gain will be determined from the maximum value of the angular separation from the earth station horizon profile at this azimuth to the profile of the minimum composite elevation angle. The procedure for calculating the minimum and maximum angular separations from the profile of the minimum composite elevation angle is given in § 1.2 of Annex IV.

The propagation mode (1) required distance is then determined using the procedures described in § 4, and the detailed methods in Annex I. Specific guidance relevant to the application of the propagation calculations is provided in § 4.4.

3 Determination of the coordination area between earth stations operating in bidirectionally allocated frequency bands

This section describes the procedures to be used for the determination of the bidirectional coordination area for an earth station transmitting in a frequency band allocated to space services in both Earth-to-space and space-to-Earth directions.

There are various coordination scenarios involving only non-time-varying antenna gains, or only time-varying antenna gains (both earth stations operate to non-geostationary space stations) or, one time-varying antenna gain and one non time-varying antenna gain.

The following subsections describe the methods for the determination of coordination area which are specific to each of these bidirectional cases. The procedures applicable to the coordination scenario where both earth stations operate to geostationary space stations are given in § 3.1. The other bidirectional coordination scenarios are considered in § 3.2, where particular attention is given to the approaches for using the horizon gain of the receiving earth station for each of the possible coordination scenarios in the appropriate procedure of § 2.

Table 3 of Annex VII provides the parameters that are to be used in the determination of the coordination area. Table 3 of Annex VII also indicates whether, in each band, the receiving earth stations operate to geostationary or non-geostationary space stations. In some bands, receiving earth stations may operate to both geostationary and non-geostationary space stations. Table 2 below indicates the number of coordination contours, which needs to be drawn for each coordination scenario and the section(s) containing the applicable calculation methods. When drawn, each coordination contour must be appropriately labelled.

TABLE 2

Coordination contours required for each bidirectional scenario

Coordinating earth station operating to a space station in the	Unknown receiving earth station operating to a space station in the	Section containing the method to determine G_t and G_r	Contours required	
			No.	Details
Geostationary orbit	Geostationary orbit	§ 3.1	1	A coordination contour comprising both propagation mode (1) and propagation mode (2) contours.
	Non-geostationary orbit	§ 3.2.1	1	A propagation mode (1) coordination contour.
	Geostationary or non-geostationary orbits*	§ 3.1.1 and § 3.2.1	2	Two separate coordination contours, one for the geostationary orbit (propagation mode (1) and mode (2) contours) and one for the non-geostationary orbit (propagation mode (1) contour).
Non-geostationary orbit	Geostationary orbit	§ 3.2.2	1	A propagation mode (1) coordination contour.
	Non-geostationary orbit	§ 3.2.3	1	A propagation mode (1) coordination contour.
	Geostationary or non-geostationary orbits*	§ 3.2.2 and § 3.2.3	2	Two separate propagation mode (1) coordination contours, one for the geostationary orbit and one for the non-geostationary orbit.

* In this case the bidirectional frequency band may contain allocations in the earth to space direction for space stations in both the geostationary orbit and non-geostationary orbits. Hence the coordinating administration will not know if the unknown receiving earth stations are operating to space stations in the geostationary orbit or non-geostationary orbit.

3.1 The coordinating and unknown earth stations operate to geostationary space stations

When both earth stations operate to space stations in the geostationary orbit, it is necessary to develop a coordination contour, comprising both propagation mode (1) and propagation mode (2) contours, using the procedures described in § 3.1.1 and § 3.1.2, respectively.

3.1.1 Determination of the coordinating earth station's propagation mode (1) contour

The procedure for the determination of the propagation mode (1) contour in this case differs from that described in § 2.2 in two ways. First, the parameters to be used for the unknown receiving earth station are those in Table 3 of Annex VII. Second and more significantly, the knowledge that both earth stations operate to geostationary satellites can be used to calculate the worst-case value of the horizon gain of the receiving earth station toward the transmitting earth station for each azimuth at the transmitting earth station. The propagation mode (1) required distance is that distance, which will result in a value of propagation mode (1) predicted path loss which is equal to the propagation mode (1) minimum required loss, $L_b(p)$ dB, as defined in § 1.3, and repeated here for convenience.

$$L_b(p) = P_t + G_t + G_r - P_r(p) \quad \text{(dB)} \tag{6}$$

where

P_t and $P_r(p)$: are as defined in § 1.3;

G_t: gain of the coordinating (transmitting) earth station antenna (dBi) towards the horizon at the horizon elevation angle and the azimuth under consideration;

G_r: the horizon gain of the unknown receiving earth station on the azimuth toward the transmitting earth station on the specific azimuth from the coordinating earth station. Values are determined by the procedure in § 2.1 of Annex V, based on parameters from Table 3 of Annex VII.

To facilitate the determination of the values of G_r to be used at an azimuth from the transmitting earth station, several simplifying approximations must be made:

– that the horizon elevation of the receiving earth station is zero degrees on all azimuths;

– that the receiving earth station operates to a space station that has zero degrees orbital inclination and may be located anywhere on the geostationary orbit that is above the minimum elevation angle, given in Table 3 of Annex VII, for the location of the receiving earth station;

– that the latitude of the receiving earth station is the same as that of the transmitting earth station;

– that plane geometry can be used to inter-relate the azimuth angles at the respective earth stations, rather than using the great circle path.

The first three assumptions provide the basis for determining the horizon gain of the receiving earth station on any azimuth. The assumption of 0° horizon elevation angle is conservative since the increase in horizon antenna gain due to a raised horizon would, in practice, be more than offset by any real site shielding[5]. The last two assumptions in the list simplify the calculation of the sum of G_t and G_r along any azimuth. Since the propagation mode (1) required distances are small, in global geometric terms, these approximations may introduce a small error in the determination of the horizon gain of the receiving earth station antenna that, in any case, will not exceed 2 dB. Because of the assumption of plane geometry, for a given azimuth at the transmitting earth station the appropriate value of the horizon gain of the receiving earth station is the value on the reciprocal (i.e., ±180 degrees, see § 2.1 of Annex V) azimuth at the receiving earth station.

The propagation mode (1) required distance is then determined using the procedures described in § 4, and the detailed methods in Annex I. Specific guidance relevant to the application of the propagation calculations is provided in § 4.4.

3.1.2 Determination of the coordinating earth station's propagation mode (2) contour

The procedure for the determination of the propagation mode (2) contour for a transmitting earth station operating to a geostationary space station uses the same simplifying approximations made in § 3.1.1, but it is based on a geometrical construction that avoids the requirement for a complex propagation model (see § 3 of Annex V). Auxiliary contours cannot be used in this method, as the calculations are not based on the propagation mode (2) required loss.

[5] While no site shielding can be assumed for the receiving earth station, any site shielding that may exist at the transmitting earth station is considered by taking into account the horizon elevation angle in accordance with § 1 of Annex I.

The propagation mode (2) contour is determined using the elevation angle and the azimuth from the coordinating transmitting earth station to the space station, together with the following two considerations:

i) the minimum coordination distance (see § 4.2), which will be the required distance for some azimuths; and

ii) a worst-case required distance determined by the hydrometeor scatter geometry for a receiving earth station located in either of two 6 degree azimuth sectors. Within these sectors the receiving earth station is assumed to be operating at the minimum elevation angle to a space station in the geostationary orbit and its main beam intersects the beam for the coordinating transmitting earth station at the point where the latter beam passes through the rain height (h_R). Although the scattering can occur anywhere between the coordinating earth station and this point, the intersection of the two beams at this point represents the worst-case interference scenario. Hence, it results in the worst-case distance requirement for receiving earth stations located in the two azimuth sectors.

For an earth station operating to a space station in an inclined orbit, the lowest expected operational antenna elevation angle and its associated azimuth are used in the calculations.

The propagation mode (2) contour is determined using the method in § 3 of Annex V.

3.2 The coordinating or unknown earth stations operate to non-geostationary space stations

For the cases where a coordinating (transmitting) earth station operates to non-geostationary space stations, the following procedures assume that the earth station is tracking the space station, otherwise see § 1.4.2. Hence to determine of the coordination area, the method described in § 2.2 is used.

Table 3 of Annex VII provides values of horizon antenna gain to be used in the calculations.

One or more of the following three procedures may be needed to determine the required propagation mode (1) coordination contours of Table 2. Propagation mode (2) contours are not required for any of the cases where either of the earth stations operates to space stations in non-geostationary orbits.

3.2.1 A coordinating earth station operates to geostationary space station with respect to unknown earth stations operating to non-geostationary space stations

When the coordinating earth station operates to a space station in the geostationary orbit and the unknown earth stations operate to space stations in non-geostationary orbits, the propagation mode (1) coordination area is determined using the procedures described in § 2.1.1. The only modification needed is to use the horizon antenna gain (G_r) of the unknown receiving earth station in place of the terrestrial station gain (G_x). The appropriate values for this gain and the appropriate system parameters are contained in Table 3 of Annex VII.

3.2.2 A coordinating earth station operates to non-geostationary space station with respect to unknown earth stations operating to geostationary space stations

When the coordinating earth station operates to space stations in non-geostationary orbits and the unknown earth stations operate to space stations in the geostationary orbit, the horizon antenna gain (G_r) for the unknown receiving earth station is determined in accordance with the simplifying approximations of § 3.1.1, as elaborated in § 1.1 of Annex V, and the parameters of Table 3 of Annex VII. Determination of the propagation mode (1) coordination area then follows the procedure of § 2.2 by using the appropriate horizon gain of the receiving earth station at each azimuth under consideration and the appropriate system parameters from Table 3 of Annex VII.

3.2.3 The coordinating and unknown earth stations operate to non-geostationary space stations

When the coordinating earth station operates to space stations in non-geostationary orbits and the unknown earth stations operate to space stations in non-geostationary orbits, the propagation mode (1) coordination area is determined using the procedure described in § 2.2. The only modification is to use the horizon antenna gain (G_r) of the unknown receiving earth station in place of the terrestrial station antenna gain. The appropriate values for this gain and the appropriate system parameters are given in Table 3 of Annex VII.

4 General considerations for the determination of the propagation mode (1) required distance

For the determination of the propagation mode (1) required distances, the applicable frequency range has been divided into three parts. The propagation calculations for the VHF/UHF frequencies between 100 MHz and 790 MHz are based upon propagation mode (1) predicted path loss curves. From 790 MHz to 60 GHz the propagation modelling uses tropospheric scatter, ducting and layer reflection/refraction models. At higher frequencies up to 105 GHz the model is based on a free-space loss and a conservative assumption for gaseous absorption. The possible range of time percentages is different in the different propagation models.

After taking site shielding (§ 1 of Annex I) into consideration, for the coordinating earth station only, the following methods are used to determine the propagation mode (1) required distances:

– For frequencies between 100 MHz and 790 MHz the method described in § 2 of Annex I.

– For frequencies between 790 MHz and 60 GHz the method described in § 3 of Annex I.

– For frequencies between 60 GHz and 105 GHz the method described in § 4 of Annex I.

The three methods referred to above rely on a value of propagation mode (1) minimum required loss, determined according to the appropriate system parameters in Table 1, 2 and 3 of Annex VII.

4.1 Radio-climatic information

For the calculation of the propagation mode (1) required distance, the world has been classified in terms of a radio-meteorological parameter representing clear-air anomalous propagation conditions. The percentage of time β_e for which these clear-air anomalous propagation conditions exist, is latitude dependent and is given by:

$$\beta_e = \begin{cases} 10^{1.67-0.015\,\zeta_r} & \text{for } \zeta_r \le 70^\circ \quad (7) \\ 4.17 & \text{for } \zeta_r > 70^\circ \quad (8) \end{cases}$$

with:

$$\zeta_r = \begin{cases} |\zeta| - 1.8 & \text{for } |\zeta| > 1.8^{\circ} \qquad (9) \\ 0 & \text{for } |\zeta| \le 1.8^{\circ} \qquad (10) \end{cases}$$

where

ζ (in degrees) is the latitude of the earth station's location

For frequencies between 790 MHz and 60 GHz the path centre sea level surface refractivity (N_0) is used in the propagation mode (1) calculations. This can be calculated using:

$$N_0 = 330 + 62.6 \exp^{-\left(\frac{\zeta - 2}{32.7}\right)^2} \qquad (11)$$

4.2 Minimum coordination distance for propagation modes (1) and (2)

The minimum coordination distance can be calculated in two steps. First calculate distance d_x using:

$$dx = 100 + \frac{(\beta_e - 40)}{2} \text{ km} \qquad (12)$$

where

β_e is given in § 4.1

Then calculate the minimum coordination distance at any frequency (f in GHz) in the range 100 MHz - 105 GHz using:

$$d_{min} = \begin{cases} 100 + \frac{(\beta_e - f)}{2} & \text{km} & \text{for } f < 40 \text{ GHz} & (13) \\ \frac{(54 - f)dx + 10(f - 40)}{14} & \text{km} & \text{for } 40 \text{ GHz} \le f < 54 \text{ GHz} & (14) \\ 10 & \text{km} & \text{for } 54 \text{ GHz} \le f < 66 \text{ GHz} & (15) \\ \frac{10(75 - f) + 45(f - 66)}{9} & \text{km} & \text{for } 66 \text{ GHz} \le f < 75 \text{ GHz} & (16) \\ 45 & \text{km} & \text{for } 75 \text{ GHz} \le f < 90 \text{ GHz} & (17) \\ 45 - \frac{(f - 90)}{1.5} & \text{km} & \text{for } 90 \text{ GHz} \le f \le 105 \text{ GHz} & (18) \end{cases}$$

The distance from which all iterative calculations start (for both propagation mode (1) and propagation mode (2)), is the minimum coordination distance (d_{min}) as given in equations (13) to (18).

4.3 Maximum coordination distance for propagation mode (1)

In the iterative calculation described in Annex I, it is necessary to set an upper limit (d_{max1}) to the propagation mode (1) coordination distance.

For frequencies less than or equal to 60 GHz and propagation paths entirely within a single Zone, the distance shall not exceed the maximum coordination distance given in Table 3 for that Zone.

For mixed paths, the required distance can comprise one or more contributions from Zones A1, A2, B and C. The aggregate distance for any one zone must not exceed the value given in Table 3. The overall required distance must not exceed the value in Table 3 for the zone in the mixed path having the largest Table 3 value. Thus a path comprising both Zones A1 and A2 must not exceed 500 km.

TABLE 3

Maximum coordination distances for propagation mode (1) for frequencies below 60 GHz

Zone	d_{max1} (km)
A1	500
A2	375
B	900
C	1 200

For frequencies above 60 GHz the maximum coordination distance d_{max1} is given by:

$$d_{max\,1} = 80 - 10 \log\left(\frac{p}{50}\right) \tag{19}$$

where

p is defined in § 1.3.

4.4 Guidance on application of propagation mode (1) procedures

As explained in § 1.3, for those cases where earth stations are sharing with terrestrial stations, it is appropriate to apply a correction factor (C_i in dB) to the worst case assumptions on system parameters and interference path geometry. This correction factor takes into account that the assumption that all the worst-case values will occur simultaneously is unrealistic when determining the propagation mode (1) required distances.

The characteristics of terrestrial systems depend on the frequency band, and the value of the correction factor to be applied follows the frequency dependence given in equation (20). At frequencies between 100 MHz and 400 MHz, and between 60 GHz and 105 GHz, sharing between earth stations and terrestrial systems is a recent development and there is little established practical experience, or opportunity to analyse operational systems. Hence, the value of the correction factor is 0 dB in these bands. Between 400 MHz and 790 MHz and between 4.2 GHz and 60 GHz the value of the correction factor is reduced in proportion to the logarithm of the frequency, as indicated in equation (20).

The value of the nominal correction to be used at any frequency f (GHz) is therefore given by:

$$X(f) = \begin{cases} 0, & f \le 0.4 \\ 3.3833X\left(\log f + 0.3979\right), & 0.4 < f \le 0.79 \\ X, & 0.79 < f \le 4.2 \\ -0.8659X\left(\log f - 1.7781\right), & 4.2 < f \le 60 \\ 0, & f > 60 \end{cases} \quad \text{dB} \qquad (20)$$

where

X: is 15 dB for a transmitting earth station and 25 dB for a receiving earth station.

In principle the value of the nominal correction, *X(f),* is distance and path independent. However, there are a number of issues relating to interference potential at the shorter distances, and it is not appropriate to apply the full nominal correction at these distances. The correction factor is therefore applied proportionally with distance along the azimuth under consideration, starting with 0 dB at d_{min}, such that the full value of *X(f)* is achieved at a nominal distance of 375 km from the earth station.

Hence, the correction is applied using the correction constant *Z(f)* dB/km where

$$Z(f) = \frac{X(f)}{375 - d_{\min}} \quad \text{dB/km} \qquad (21)$$

The correction factor C_i (dB) is calculated in equations (I-6b) and (I-31) from the correction constant Z(*f*) (dB/km).

At distances greater than 375 km, the correction factor C_i to be applied is the value of C_i at 375 km distance.

In addition, the correction factor is applied to its highest value only on land paths. The correction factor is 0 dB for wholly sea paths. A proportion of the correction factor is applied on mixed paths. The amount of correction to be applied to a particular path is determined by the path description parameters used for the propagation mode (1) calculation (correction factors C_i and C_{2i} in § 2 and § 3 respectively of Annex I). As the correction factor is distance dependent it is applied automatically within the iterative calculation used to determine the propagation mode (1) required distance (see Annex I).

The correction factor does not apply to the bidirectional case and therefore in the determination of the bidirectional coordination contour:

$$Z(f) = 0 \text{ dB/km}$$

For the determination of propagation mode (1) auxiliary contours, the propagation mode (1) minimum required loss $L_b(p)$ for p per cent of time (see § 1.3) equation (1) is replaced by:

$$L_{bq}(p) = L_b(p) + Q \quad \text{dB} \qquad (22)$$

where

Q: is the auxiliary contour value in dB

Note that auxiliary contour values are assumed to be negative (i.e. –5, –10, –15, –20 dB etc.).

5 General considerations for the determination of the propagation mode (2) required distance

The determination of the contour for scattering from hydrometeors (e.g., rain scatter) is predicted on a path geometry that is substantially different from that of the great-circle propagation mechanisms. Hydrometeor scatter can occur where the beams of the earth station and the terrestrial station intersect (partially or completely) at, or below, the rain height h_R (see § 3 of Annex II). It is assumed that at heights above this rain height the effect of scattering will be suppressed by additional attenuation, and it will not, therefore, contribute significantly to the interference potential. For the determination of the propagation mode (2) contour, it is assumed that the main beams of any terrestrial stations exactly intersect the main beam of the coordinating earth station. The mitigating effects of partial beam intersections can be determined using propagation mode (2) auxiliary contours.

Since, to a first approximation, microwave energy is scattered isotropically by rain, interference can be considered to propagate equally at all azimuths around the common volume centred at the beam intersection (see § 1.3). Generally, the beam intersection will not lie on the great-circle path between the two stations. The common volume can therefore result from terrestrial stations located anywhere around the earth station, including those behind the earth station.

The propagation mode (2) contour is a circle with a radius equal to the propagation mode (2) required distance. Unlike the case for propagation mode (1), the propagation mode (2) contour is not centred on the earth station’s physical location, instead it is centred on a point on the earth’s surface immediately below the centre of the common volume.

A common volume can exist, with equal probability, at any point along the earth station beam between the earth station’s location and the point at which the beam reaches the rain height. To provide appropriate protection for/from terrestrial stations[6], the centre of the common volume is assumed to be half way between the earth station and the point at which its beam intersects the rain height. The distance between the projection of this point on to the earth surface and the location of the earth station is known as Δd (see § 4 of Annex II). The centre of the propagation mode (2) contour is therefore Δd km from the earth station on the azimuth of the earth station’s main beam axis.

5.1 The required distance for propagation mode (2)

Propagation mode (2) required distances are measured along a radial originating at the centre of the rain scatter common volume. The calculation requires iteration for distance, starting at the same minimum distance defined for propagation mode (1) until either the required propagation mode (2) minimum required loss, or a latitude-dependent propagation mode (2) maximum calculation distance, is achieved. The propagation mode (2) calculations use the method described in Annex II. The calculations only need to be performed in the frequency range 1 000 MHz to 40.5 GHz. Outside this frequency range, rain scatter interference can be neglected and the propagation mode (2) required distance is set to the minimum coordination distance given by equations (13) to (18).

---

[6] This procedure does not apply for the case of an earth sharing a frequency band with other earth station operating in the opposite direction of transmission, as for that specific case the propagation mode (2) contour is based on a geometric construction.

ANNEX I

Determination of the required distance for propagation mode (1)

1 Adjustments for earth station horizon elevation angle and distance

For propagation mode (1), the required distance depends on the characteristics of the physical horizon around the earth station. The horizon is characterised by the horizon distance d_h (see below), and the horizon elevation angle θ_h. The horizon elevation angle is defined here as the angle (in degrees), viewed from the centre of the earth station antenna, between the horizontal plane and a ray that grazes the physical horizon in the direction concerned. The value of θ_h is positive when the physical horizon is above the horizontal plane and negative when it is below.

It is necessary to determine horizon elevation angles and distances for all azimuths around an earth station. In practice it will generally suffice to do this in azimuth increments of 5°. However, every attempt should be made to identify, and take into consideration, minimum horizon elevation angles that may occur between those azimuths examined in 5° increments.

For the purposes of the determination of the propagation mode (1) required distance it is useful to separate the propagation effects related to the local horizon around the earth station which, on some or all azimuths, may be determined by nearby hills or mountains, from the propagation effects on the remainder of the path. This is achieved by referencing the propagation model to a 0° horizon elevation angle for the coordinating earth station, and then to include a specific term A_h to deal with the known horizon characteristics of the earth station being coordinated. Where appropriate, A_h modifies the value of the path loss, on each azimuth, from which the propagation mode (1) required distance is derived.

There are two considerations to be taken into account that can change the level of attenuation for the propagation mode (1) path loss for the reference 0° case.

- The first is where the coordinating earth station has a positive horizon elevation angle (on a particular azimuth). In this case it will benefit from additional diffraction propagation losses over the horizon (generally referred to as site shielding). In this case the attenuation A_h is positive and reduces the value of path loss that is required, compared to the reference 0° horizon elevation angle case (see equations (I-5a) and (I-5b)).
- The second situation is where the coordinating earth station is at a location above the local foreground, and has a negative (downward) horizon elevation angle on a particular azimuth. In this case a measure of additional protection is necessary because the path angular distance along the radial is reduced and hence the path loss for a given distance will be lower than for the zero degree elevation angle case. It is convenient to deal with this effect as part of the site shielding calculation. Hence, in this case the attenuation A_h will be negative and it increases the value of the path loss that is required, compared to the reference 0° horizon elevation angle case.

The contribution made by the attenuation arising from the coordinating earth station's horizon characteristics to the propagation mode (1) minimum required loss modifies the value of path loss that then needs to be determined in the three propagation mode (1) models. The attenuation A_h is calculated for each azimuth around the coordinating earth station as follows.

The distance of the horizon (d_h), from the earth station's location, is determined by:

$$d_h = \begin{cases} 0.5\text{ km} & \text{if no information is available about the horizon distance, or if the distance is} < 0.5\text{ km.} \\ \text{horizon distance (km)} & \text{if this is within the range } 0.5\text{ km} \le \text{horizon distance} \le 5.0\text{ km.} \\ 5.0\text{ km} & \text{if the horizon distance is} > 5.0\text{ km.} \end{cases}$$

The contribution made by the horizon distance d_h to the total site shielding attenuation is given by A_d in dB for each azimuth using:

$$A_d = 15\left[1 - \exp\left(\frac{0.5 - d_h}{5}\right)\right]\left[1 - \exp\left(-\varepsilon_h f^{1/3}\right)\right] \qquad \text{dB} \qquad \text{(I-1)}$$

where

f: throughout this appendix is in GHz.

The total site shielding attenuation along each azimuth from the coordinating earth station is given by:

$$A_h = \begin{cases} 20\log(1 + 4.5\varepsilon_h f^{1/2}) + \varepsilon_h f^{1/3} + A_d & \text{dB} & \text{for } \varepsilon_h \ge 0^{\circ} & \text{(I-2a)} \\ 3[(f+1)^{1/2} - 0.0001 f - 1.0487]\varepsilon_h & \text{dB} & \text{for } 0^{\circ} > \varepsilon_h \ge -0.5^{\circ} & \text{(I-2b)} \\ -1.5[(f+1)^{1/2} - 0.0001 f - 1.0487] & \text{dB} & \text{for } \varepsilon_h < -0.5^{\circ} & \text{(I-2c)} \end{cases}$$

The value of A_h must be limited to satisfy the conditions:

$$-10 \le A_h \le (30 + \varepsilon_h) \qquad \text{(I-3)}$$

In equations I-1, I-2 and I-3 the value of ε_h must always be expressed in degrees. The limits defined in equation (I-3) are specified because protection outside these limits may not be realized in practical situations.

2 Frequencies between 100 MHz and 790 MHz

The propagation model given in this section is limited to an average annual time percentage (*p*) in the range 1% to 50%.

An iterative process is used to determine the propagation mode (1) required distance. First, equation I-5 is evaluated. Then commencing at the minimum coordination distance, d_{min}, given by the method described in § 1.5.3 of the main body of the Appendix, equations I-6 to I-9 are iterated for distances d_i (where i = 0,1,2..etc.) incremented in steps of s (km) as described in § 1.3 of the main body of the Appendix. In each iteration d_i is referred to as the current distance. This process is continued until either of the following expressions becomes true:

$$L_2(p_1) \geq \begin{cases} L_1(p) & \text{for the main, or supplementary, contour} \\ L_{1q}(p) & \text{for the auxiliary contour} \end{cases} \tag{I-4a}$$

or:

$$d_i \geq \begin{cases} d_{max1} & \text{for the main, or supplementary, contour} \\ d_1 & \text{for the auxiliary contour} \end{cases} \tag{I-4b}$$

The required distance, d_1, or the auxiliary contour distance d_q are then given by the current distance for the last iteration: i.e.

$$d_1 = d_i \tag{I-4c}$$

or:

$$d_q = d_i \tag{I-4d}$$

As the eventual mix of zones along a path is unknown, all paths are treated as if they are potential land and sea paths. Parallel calculations are undertaken, the first assuming the path is all land and a second assuming it is all sea. A non-linear interpolation is then performed, the output of which depends upon the current mix of land and sea losses in the distance d_i. Where the current mix along the path includes sections of both warm sea and cold sea zones, all the sea along that path is assumed to be warm sea.

For the main, or supplementary, contour:

$$L_1(p) = L_b(p) - A_h \tag{I-5a}$$

For an auxiliary contour:

$$L_{1q}(p) = L_{bq}(p) - A_h \tag{I-5b}$$

where

$L_b(p)$ dB and $L_{bq}(p)$ Db are the minimum required loss required for p% of the time for the main, or supplementary, contour and the auxiliary contour of value Q dB respectively (see § 1.3 and § 1.6 of the main body of the Appendix).

Iterative calculations:

At the start of each iteration calculate the current distance for i = 0,1,2, etc.:

$$d_i = d_{\min} + i.s \tag{I-6a}$$

The correction factor, C_i dB, (see § 4.4 of the main body of the Appendix) for the distance d_i is given by:

$$C_i = \begin{cases} Z(f)(d_i - d_{min})\ (\text{dB}) & \text{for the main, or supplementary, contour} \\ 0\ (\text{dB}) & \text{for the auxiliary contour} \end{cases} \tag{I-6b}$$

where

$Z(f)$ is given by equation (21) in § 4.4 of the main body of the Appendix.

At distances greater than 375 km the value of the correction factor (C_i in equation I-6b) to be applied, is the value of C_i at the 375 km distance.

The loss, $L_{bl}(p)$ for the assumption of the path being wholly land (Zones A1 or A2) is evaluated successively using:

$$L_{bl}(p) = 142.8 + 20\log f + 10\log p + 0.1 d_i + C_i \tag{I-7}$$

The loss, $L_{bs}(p)$, for the assumption of the path being wholly cold sea (Zone B) or warm sea (Zone C) is evaluated successively using:

$$L_{bs}(p_1) = \begin{cases} \left.\begin{array}{l} 49.91\log(d_i + 1840 f^{1.76}) + 1.195 f^{0.393} (\log p)^{1.38} d_i^{0.597} \\ \quad + (0.01 d_i - 70)(f - 0.1581) + (0.02 - 2\,\mathrm{x}10^{-5} p^2) d_i \\ \qquad + 9.72\ 10^{-9} d_i^2 p^2 + 20.2 \end{array}\right\} \text{for Zone (B)} & \text{(I-8a)} \\ \left.\begin{array}{l} 49.343\log(d_i + 1840 f^{1.58}) + 1.266(\log p)^{(0.468+2.598 f)} d_i^{0.453} \\ + (0.037 d_i - 70)(f - 0.1581) + 1.95\,\mathrm{x}10^{-10} d_i^2 p^3 + 20.2 \end{array}\right\} \text{for Zone (C)} & \text{(I-8b)} \end{cases}$$

The predicted path loss at the current distance is then given by:

$$L_2(p) = L_{bs}(p) + \left[1 - \exp\left(-5.5\left(\frac{d_{tm}}{d_i}\right)^{1.1}\right)\right] \cdot \left(L_{bl}(p) - L_{bs}(p)\right) \tag{I-9}$$

where

d_{tm} (km): is the longest continuous land (inland + coastal) distance, i.e. Zone A1 + Zone A2 within the current path distance.

3 Frequencies between 790 MHz and 60 GHz

The propagation model given in this section is limited to an average annual time percentage (p_1) in the range 0.001% to 50%.

An iterative process is used to determine the propagation mode (1) required distance. First, equations I-11 to I-21 are evaluated. Then, commencing at the minimum coordination distance, d_{min}, equations I-22 to I-32 are iterated for distances d_i, where i = 0,1,2..etc., incremented in steps of s (km) as described in § 1.3 of the main body of the Appendix. For each iteration d_i is referred to as the current distance. This process is continued until either of the following expressions becomes true:

$$\begin{cases} (L_5(p) \geq L_3(p)) \text{ AND } (L_6(p) \geq L_4(p)) & \text{for the main, or supplementary, contour} \\ (L_5(p) \geq L_{3q}(p)) \text{ AND } (L_6(p) \geq L_{4q}(p)) & \text{for the auxiliary contour} \end{cases} \tag{I-10a}$$

or:

$$d_i \geq \begin{cases} d_{max1} & \text{for the main, or supplementary, contour} \\ d_1 & \text{for the auxiliary contour} \end{cases} \tag{I-10b}$$

The required distance, d_1, or the auxiliary contour distance, d_q is then given by the current distance for the last iteration, i.e.

$$d_1 = d_i \tag{I-10c}$$

or:

$$d_q = d_i \tag{I-10d}$$

The specific attenuation due to gaseous absorption

Calculate the specific attenuation (dB/km) due to dry air:

$$\gamma_o = \begin{cases} \left[7.19 \times 10^{-3} + \dfrac{6.09}{f^2 + 0.227} + \dfrac{4.81}{(f - 57)^2 + 1.50} \right] f^2 \times 10^{-3} & \text{for } f \leq 56.77 \text{ GHz} \quad \text{(I-11a)} \\ 10 & \text{for } f > 56.77 \text{ GHz} \quad \text{(I-11b)} \end{cases}$$

The specific attenuation due to water vapour is given as a function of ρ (the water vapour density in units of g/m^3) by the following equation:

$$\gamma_w(\rho) = \left(0.050 + 0.0021\rho + \frac{3.6}{(f - 22.2)^2 + 8.5} \right) f^2 \rho \times 10^{-4} \tag{I-12}$$

Calculate the specific attenuation (dB/km) due to water vapour for the troposcatter propagation model using a water vapour density of 3.0 g/m^3:

$$\gamma_{wt} = \gamma_w\,(3.0) \tag{I-13a}$$

Calculate the specific attenuation (dB/km) due to water vapour for the ducting propagation model using a water vapour density of 7.5 g/m^3 for paths over land, Zones A1 and A2, using:

$$\gamma_{wdl} = \gamma_w\,(7.5) \tag{I-13b}$$

Calculate the specific attenuation (dB/km) due to water vapour for the ducting propagation model using a water vapour density of 10.0 g/m^3 for paths over sea, Zones B and C, using:

$$\gamma_{wds} = \gamma_w\,(10.0) \tag{I-13c}$$

Note that the value of 10 g/m^3 is used for both zones B and C in view of the lack of data on the variability of water vapour density on a global basis, particularly the minimum values.

Calculate the frequency-dependent ducting specific attenuation (dB/km):

$$\gamma_d = 0.05 f^{1/3} \tag{I-14}$$

For the ducting model:

Calculate the reduction in attenuation arising from direct coupling into over-sea ducts (dB):

$$A_c = \frac{-6}{(1 + d_c)} \qquad \text{(I-15)}$$

where

d_c (km): is the distance from a land based earth station to the coast in the direction being considered;

d_c: is zero in other circumstances.

Calculate the minimum loss to be achieved within the iterative calculations:

$$A_1 = 122.43 + 16.5 \log f + A_h + A_c \qquad \text{(I-16)}$$

For the main, or supplementary, contour:

$$L_3(p) = L_b(p) - A_1 \qquad \text{(I-17a)}$$

For an auxiliary contour:

$$L_{3q}(p) = L_{bq}(p) - A_1 \qquad \text{(I-17b)}$$

where

$L_b(p)$ dB and L_{bq} (p) dB are the minimum required loss required for p% of the time for the main, or supplementary, contour and the auxiliary contour of value Q dB respectively (see § 1.3 and § 1.6 of the main body of the Appendix).

For the tropospheric scatter model:

Calculate the frequency-dependent part of the losses (dB):

$$L_f = 25 \log(f) - 2.5 \left[\log\left(\frac{f}{2} \right) \right]^2 \qquad \text{(I-19)}$$

Calculate the non-distance-dependent part of the losses (dB):

$$A_2 = 187.36 + 10\varepsilon_h + L_f - 0.15\, N_0 - 10.1 \left(-\log\left(\frac{p}{50} \right) \right)^{0.7} \qquad \text{(I-20)}$$

where

ε_h: is the earth station horizon elevation angle in degrees;

N_0: is the path centre sea level surface refractivity (see equation 11, § 4.1 to the main body of the Appendix).

Calculate the minimum required value for the distance dependent losses (dB):

For the main, or supplementary, contour:

$$L_4(p) = L_b(p) - A_2 \qquad \text{(I-21a)}$$

For an auxiliary contour:

$$L_{4q}(p) = L_{bq}(p) - A_2 \qquad \text{(I-21b)}$$

where

$L_b(p)$ dB and L_{bq} (p) dB are the minimum required loss required for p% of the time for the main, or supplementary, contour and the auxiliary contour of value Q dB respectively (see § 1.3 and § 1.6 of the main body of the Appendix).

Iterative calculations:

At the start of each iteration calculate the current distance for i = 0,1,2..etc.:

$$d_i = d_{\min} + i.s \qquad \text{(I-22)}$$

Calculate the specific attenuation due to gaseous absorption (dB/km):

$$\gamma_g = \gamma_o + \gamma_{wdl}\left(\frac{d_t}{d_i}\right) + \gamma_{wds}\left(1 - \frac{d_t}{d_i}\right) \qquad \text{(I-23)}$$

where

d_t (km): is the current aggregate land distance, Zone A1 + Zone A2, within the current path distance.

Calculate the following zone-dependent parameters:

$$\tau = 1 - \exp\left(-\left(4.12 \times 10^{-4}\,(d_{lm})^{2.41}\right)\right) \qquad \text{(I-24)}$$

where

d_{lm} (km): is the longest continuous inland distance, Zone A2, within the current path distance;

$$\mu_1 = \left[10^{\frac{-d_{tm}}{16-6.6\tau}} + \left[10^{-(0.496+0.354\tau)}\right]^5\right]^{0.2} \qquad \text{(I-25)}$$

where

d_{tm} (km): is the longest continuous land (i.e. inland + coastal) distance, Zone A1 + Zone A2 within the current path distance.

μ_1 shall be limited to $\mu_1 \leq 1$.

$$\sigma = -0.6 - 8.5 \times 10^{-9}\, d_i^{3.1}\, \tau \qquad \text{(I-26)}$$

σ shall be limited to $\sigma \geq -3.4$.

$$\mu_2 = \left(2.48 \times 10^{-4} \, d_i^2\right)^{\sigma} \tag{I-27}$$

μ_2 shall be limited to $\mu_2 \leq 1$.

$$\mu_4 = \begin{cases} 10^{(-0.935 + 0.0176\,\zeta_r)\log \mu_1} & \text{for } \zeta_r \leq 70^{\text{o}} \quad \text{(I-28a)} \\ 10^{0.3 \log \mu_1} & \text{for } \zeta_r > 70^{\text{o}} \quad \text{(I-28b)} \end{cases}$$

where

ζ_r: is given in equations 9 and 10, § 4.1 to the main body of the Appendix.

Calculate the path-dependent incidence of ducting (β) and a related parameter (Γ_1) used to calculate the time dependency of the path loss:

$$\beta = \beta_e . \mu_1 . \mu_2 . \mu_4 \tag{I-29}$$

where

β_e is given in equations 7 and 8, § 4.1 to the main body of the Appendix.

$$\Gamma_1 = \frac{1.076}{(2.0058 - \log \beta)^{1.012}} \exp\left(-(9.51 - 4.8 \log \beta + 0.198 (\log \beta)^2) \times 10^{-6} d_i^{1.13}\right) \tag{I-30}$$

Calculate the correction factor, C_{2i} dB, (see § 4.4 to the main body of the Appendix) using:

$$C_{2i} = \begin{cases} Z(f)(d_i - d_{min})\tau \quad \text{(dB)} & \text{for the main, or supplementary, contour} \\ 0 \quad \text{(dB)} & \text{for the auxiliary contour} \end{cases} \tag{I-31}$$

where

$Z(f)$ is calculated using (equation 21) in § 4.4 to the main body of the Appendix.

At distances greater than 375 km the value of the correction factor (C_{2i} in equation I-31) to be applied, is the value of C_{2i} at the 375 km distance.

Calculate the distance-dependent part of the losses (dB) for ducting:

[illegible] $+ \, C_{2i}$ (I-32)

and for tropospheric scatter:

$$L_6(p) = 20 \log(d_i) + 5.73 \times 10^{-4} (112 - 15 \cos(2\zeta)) d_i + (\gamma_o + \gamma_{wt}) d_i + C_{2i} \tag{I-33}$$

For the determination of distances for auxiliary contours, $C_{2i} = 0$ dB.

4 Frequencies between 60 GHz and 105 GHz

This propagation model is valid for average annual percentage time (p) in the range from 0.001% to 50%.

An iterative process is used to determine the propagation mode (1) required distance. First, equations I-34 to I-38 are evaluated. Then commencing at the minimum coordination distance, d_{min}, equations I-39 and I-40 are iterated for distances d_i, where i = 0,1,2..etc., incremented in steps of s km as described in § 1.3 of the main body of the Appendix. For each iteration d_i is referred to as the current distance.

This process is continued until either of the following expressions becomes true:

$$L_9(p) \geq \begin{cases} L_8(p) & \text{for the main, or supplementary, contour} \\ L_{8q}(p) & \text{for the auxiliary contour} \end{cases} \qquad \text{(I-33a)}$$

or:

$$d_i \geq \begin{cases} d_{max1} & \text{for the main, or supplementary, contour} \\ d_1 & \text{for the auxiliary contour} \end{cases} \qquad \text{(I-33b)}$$

The required distance, d_1, or the auxiliary contour distance d_q are then given by the current distance for the last iteration: i.e.

$$d_1 = d_i \qquad \text{(I-33c)}$$

or:

$$d_q = d_i \qquad \text{(I-33d)}$$

Calculate the specific attenuation in dB/km for dry air in the frequency range 60 GHz to 105 GHz using:

$$\gamma_{om} = \begin{cases} \left[2 \times 10^{-4} \left(1 - 1.2 \times 10^{-5} f^{\,1.5}\right) + \dfrac{4}{(f-63)^2 + 0.936} + \dfrac{0.28}{(f-118.75)^2 + 1.771} \right] f^2\, 6.24 \times 10^{-4} \text{ dB/km} & \text{for } f > 63.26 \text{ GHz} \qquad \text{(I-34a)} \\ 10 \text{ dB/km} & \text{for } f \leq 63.26 \text{ GHz} \qquad \text{(I-34b)} \end{cases}$$

Calculate the specific attenuation in dB/km for an atmospheric water vapour density of 3 g/m^3 using:

$$\gamma_{wm} = \left(0.039 + 7.7 \times 10^{-4} f^{\,0.5}\right) f^2\, 2.369 \times 10^{-4} \qquad \text{(I-35)}$$

Calculate a conservative estimate of the specific attenuation in dB/km for gaseous absorption using:

$$\gamma_{gm} = \gamma_{om} + \gamma_{wm} \quad \text{dB/km} \qquad \text{(I-36)}$$

For the required frequency, and the value of earth station site shielding, A_h dB, as calculated using the method described in § 1 of this Annex, calculate the minimum loss to be achieved in the iterative calculations.

$$L_7 = 92.5 + 20 \log(f) + A_h \quad \text{dB} \qquad \text{(I-37)}$$

For the main, or supplementary, contour:

$$L_8(p) = L_b(p) - L_7 \qquad \text{dB} \qquad \text{(I-38a)}$$

For an auxiliary contour:

$$L_{8q}(p) = L_{bq}(p) - L_7 \qquad \text{dB} \qquad \text{(I-38b)}$$

where

$L_b(p)$ dB and $L_{bq}(p)$ dB are the minimum required loss required for p% of the time for the main or supplementary contour and the auxiliary contour of value Q dB respectively (see § 1.3 and § 1.6 of the main body of the Appendix).

Iterative calculations:

At the start of each iteration calculate the current distance for i = 0,1,2 etc.:

$$d_i = d_{min} + i.s \qquad \text{(I-39)}$$

Calculate the distance-dependent losses for the current distance:

$$L_9(p) = \gamma_{gm} d_i + 20\log(d_i) + 2.6\left[1 - \exp\left(\frac{-d_i}{10}\right)\right]\log\left(\frac{p}{50}\right) \qquad \text{(I-40)}$$

For frequencies above 60 GHz the correction factor (see § 4.4 of the main body of the Appendix) is 0 dB. Therefore a correction term has not been added to equation (I-40).

ANNEX II

Determination of the required distance for propagation mode (2)

1 Overview

The algorithm given below allows propagation mode (2) path loss, $L_r(p)$ (dB), to be obtained as a monotonic function of rainfall rate, $R(p)$ (mm/h), and with the hydrometeor scatter distance, r_i (km), as a parameter. The model is valid for average annual time percentage (p) in the range 0.001 to 10%. The procedure to determine the hydrometeor scatter contour is as follows:

a) The value of $R(p)$, is determined for the appropriate rain climatic Zones A to Q.

b) Values of $L_r(p)$, are then calculated for incremental values of r_i, starting at the minimum coordination distance d_{min}, in steps of s (km), as described in § 1.3 of the main body of the Appendix. The correct value of r_i is that for which the corresponding value of $L_r(p)$ equals or exceeds the propagation mode (2) minimum required loss L(p). This value of r_i is the propagation mode (2) required distance and is denoted d_r .

c) If the iterative calculation results in r_i equalling or exceeding the appropriate maximum calculation distance (d_{max2}) given in § 2, then the calculation is terminated and d_r is assumed to be equal to d_{max2}. Hence the iteration stops when either of the following expressions becomes true:

$$L_r(p) \geq L(p) \qquad \text{(II-1a)}$$

or:

$$r_i \geq d_{\max 2} \qquad \text{(II-1b)}$$

d) The contour for propagation mode (2) is a circle of radius d_r (km) centred on a point along the azimuth of the earth station antenna main beam at a horizontal distance of Δd (km) from the earth station.

2 Maximum calculation distance

As discussed in § 1.5.3 of the main body of the Appendix, it is necessary to set upper limits to the maximum distance used in the iterative calculation of the required distance. The maximum calculation distance to be used for propagation mode (2) (d_{max2}) is latitude dependent and is given in the following equation:

$$d_{max2} = \sqrt{17\,000(h_R + 3)} \text{ (km)}$$

where

h_R is defined in equations II-13 and II-14.

3 Calculation of the propagation mode (2) contour

Determine $R(p)$, the rainfall rate (mm/h) exceeded on average for p% of a year. The world has been divided into a number of rain climatic zones (see Figures II-1, II-2 and II-3) which show different precipitation characteristics.

The curves shown in Figure II-4 represent consolidated rainfall-rate distributions, each applicable to several of these rain climatic Zones.

Determine which rain climatic Zone is applicable to the location of the earth station:

– For 0.001% < p < 0.3% and the applicable rain climatic Zone:

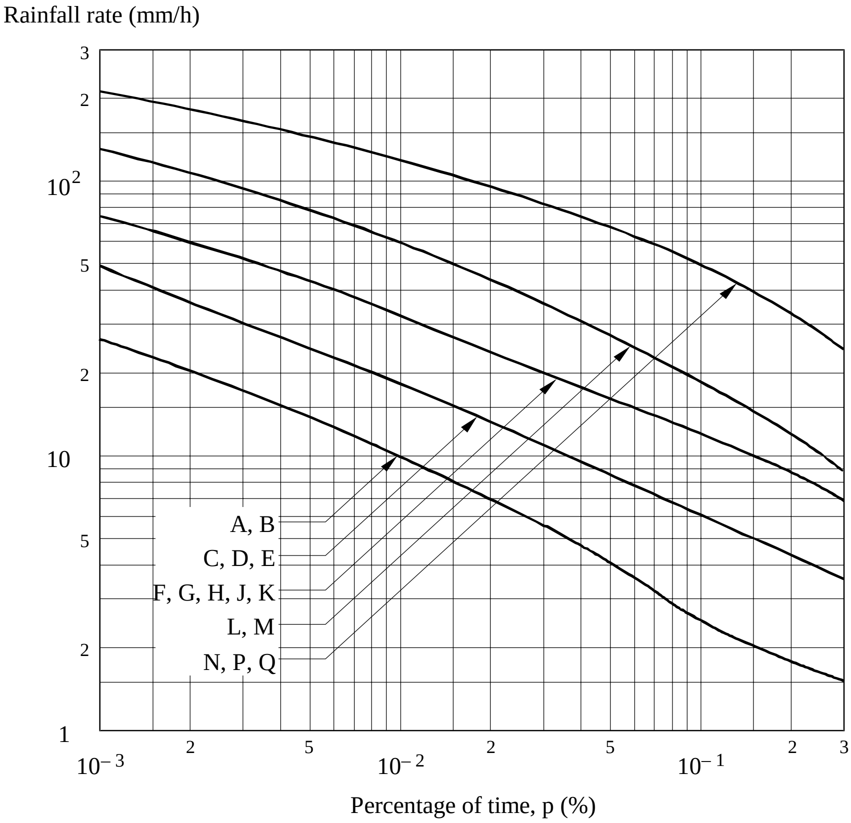
Determine $R(p)$ either from Figure II-4 or from equations (II-2, II-3, II-4, II-5, II-6).

– For $p \geq 0.3\%$:

Use equation (II-7) with values of $R(0.3\%)$ and p_c obtained from Table II-1.

FIGURE II-4

Consolidated cumulative distributions of rainfall rate for the rain climatic zones shown in Figures II-1, II-2 & II-3



0620-01

Rain climatic Zones A, B

$$R(p) = 1.1p^{-0.465} + 0.25\left[\log(p/0.001)\log^3(0.3/p)\right] - \left[\left|\log(p/0.1)\right| + 1.1\right]^{-2} \quad \text{(II-2)}$$

Rain climatic Zones C, D, E

$$R(p) = 2\ p^{-0.466} + 0.5\left[\log(p/0.001)\log^3(0.3/p)\right] \quad \text{(II-3)}$$

Rain climatic Zones F, G, H, J, K

$$R(p) = 4.17\ p^{-0.418} + 1.6\left[\log(p/0.001)\log^3(0.3/p)\right] \quad \text{(II-4)}$$

Rain climatic Zones L, M

$$R(p) = 4.9\ p^{-0.48} + 6.5\left[\log(p/0.001)\log^2(0.3/p)\right] \qquad \text{(II-5)}$$

Rain climatic Zones N, P, Q

$$R(p) = 15.6\left(p^{-0.383} + \left[\log(p/0.001)\log^{1.5}(0.3/p)\right]\right) \qquad \text{(II-6)}$$

TABLE II-1

Values of R and p_c for the different rain climatic Zone

Rain climatic zone	R (0.3%) (mm/h)	p_C (%)
A, B	1.5	2
C, D, E	3.5	3
F, G, H, J, K	7.0	5
L, M	9.0	7.5
N, P, Q	25.0	10

where

p_C %: is the reference time percentage above which the rainfall rate R(p) can be assumed to be zero.

$$R(p) = R(0.3\%)\left[\frac{\log(p_c/p)}{\log(p_c/0.3)}\right]^2 \qquad \text{(II-7)}$$

Determine the specific attenuation (dB/km) due to rain using values of k and α from Table II-2 in equation II-9. Values of k and α at frequencies other than those in Table II-2 can be obtained by interpolation using a logarithmic scale for frequency, a logarithmic scale for k and a linear scale for α.

TABLE II-2

Values of k and α for vertical polarization as a function of the frequency

Frequency (GHz)	k	α
1	0.000 0352	0.880
4	0.000 591	1.075
6	0.001 55	1.265
8	0.003 95	1.31
10	0.008 87	1.264
12	0.016 8	1.20
14	0.029	1.15
18	0.055	1.09
20	0.069 1	1.065
22.4	0.090	1.05
25	0.113	1.03
28	0.150	1.01
30	0.167	1.00
35	0.233	0.963
40	0.310	0.929
40.5	0.318	0.926

let: $$R = R(p) \qquad \text{(II-8)}$$

Then the specific attenuation (dB/km) due to rain is given by:

$$\gamma_R = k\, R^{\alpha} \tag{II-9}$$

Calculate the effective diameter of the rain cell.

$$d_s = 3.5\, R^{-0.08} \tag{II-10}$$

Then, calculate the effective scatter transfer function.

$$R_{cv} = \frac{2.17}{\gamma_R d_s}\left(1 - 10^{\frac{-\gamma_R d_s}{5}}\right) \tag{II-11}$$

Calculate the additional attenuation outside the common volume.

$$\Gamma_2 = 631 k R^{(\alpha - 0.5)} \times 10^{-(R+1)^{0.19}} \tag{II-12}$$

Determine the rain height above ground, h_R (km):

For North America and Europe west of 60° E longitude:

$$h_R = 3.2 - 0.075\,(\zeta - 35) \qquad \text{for} \quad 35 \le \zeta \le 70 \tag{II-13}$$

where

ζ is the latitude of the coordinating earth station.

For all other areas of the world:

$$h_R = \begin{cases} 5 - 0.075(\zeta - 23) & \text{for } \zeta > 23 \text{ northern hemisphere} \quad \text{(II-14a)} \\ 5 & \text{for } 0 \le \zeta \le 23 \text{ northern hemisphere} \quad \text{(II-14b)} \\ 5 & \text{for } 0 \ge \zeta \ge -21 \text{ southern hemisphere} \quad \text{(II-14c)} \\ 5 + 0.1(\zeta + 21) & \text{for } -71 \le \zeta < -21 \text{ southern hemisphere} \quad \text{(II-14d)} \\ 0 & \text{for } \zeta < -71 \text{ southern hemisphere} \quad \text{(II-14e)} \end{cases}$$

Determine the specific attenuation due to water vapour absorption (a water vapour density of 7.5 g/m^3 is used):

$$\gamma_{wr} = \left[0.06575 + \frac{3.6}{(f - 22.2)^2 + 8.5}\right] f^2\, 7.5 \times 10^{-4} \tag{II-15}$$

3.1 Iterative calculations:

Evaluate equations II-16 to II-21 inclusive for increasing values of r_i , where r_i is the current distance (km) between the region of maximum scattering and the possible location of a terrestrial station and i = 0,1,2..etc. Continue this process until either of the conditions given in equations II-1a and II-1b is true. Then the rain-scatter required distance d_r is the current value of r_i .

$$r_i = d_{\min} + i.s \tag{II-16}$$

Determine the loss above the rain height, L_{ar} (dB), applicable to scatter coupling:

$$L_{ar} = \begin{cases} 6.5\left[6(r_i - 50)^2 \times 10^{-5} - h_R\right] & \text{for } 6(r_i - 50)^2 \times 10^{-5} > h_R \quad \text{(II-17a)} \\ 0 & \text{for } 6(r_i - 50)^2 \times 10^{-5} \le h_R \quad \text{(II-17b)} \end{cases}$$

Calculate the additional attenuation for the departure from Rayleigh scattering.

$$A_b = \begin{cases} 0.005\,(f - 10)^{1.7}\,R^{0.4} & \text{for } 10 \text{ GHz} < f < 40.5 \text{ GHz} \quad \text{(II-18a)} \\ 0 & \text{for } f \le 10 \text{ GHz or when } L_{ar} \ne 0 \quad \text{(II-18b)} \end{cases}$$

Calculate the effective path length for oxygen absorption.

$$d_0 = \begin{cases} 0.7\,r_i + 32 & \text{for } r_i < 340 \text{ km} \quad \text{(II-19a)} \\ 270 & \text{for } r_i \ge 340 \text{ km} \quad \text{(II-19b)} \end{cases}$$

Calculate the effective path length for water vapour absorption.

$$d_v = \begin{cases} 0.7\,r_i + 32 & \text{for } r_i < 240 \text{ km} \quad \text{(II-20a)} \\ 200 & \text{for } r_i \ge 240 \text{ km} \quad \text{(II-20b)} \end{cases}$$

Determine the propagation mode (2) path loss, L_r (dB):

$$L_r = 168 + 20\log r_i - 20\log f - 13.2\log R - G_x + A_b - 10\log R_{cv} + \Gamma_2 + L_{ar} + \gamma_o d_0 + \gamma_{wr} d_v \quad \text{(II-21)}$$

where

γ_o: is given in equation I-11 and

G_x: is the terrestrial network antenna gain in Tables 1 or 2 of Annex VII.

4 Construction of the propagation mode (2) contour

In order to determine the centre of the circular propagation mode (2) contour, it is necessary to calculate the horizontal distance to this point from the earth station, along the azimuth of the earth station antenna main beam axis. The distance, Δd (km), to the centre of the propagation mode (2) contour is given by:

$$\Delta d = \frac{h_R}{2 \tan \varepsilon_s} \quad \text{(II-23)}$$

where

ε_s: is the earth station antenna main beam axis elevation angle and Δd shall be limited to the distance (d_r – 50) km.

The propagation mode (2) required distance d_r must lie within the range between the minimum coordinating distance d_{min}, and the propagation mode (2) maximum calculation distance d_{max2}.

Draw the propagation mode (2) contour as a circle of radius d_r km around the centre determined above. The propagation mode (2) contour is the locus of points on this circle. However, if any part of the propagation mode (2) contour falls within the contour defined by the minimum coordination distance, this arc of the propagation mode (2) contour is taken to be identical to the contour based on the minimum coordination distance and the propagation mode (2) contour is then no longer circular.

ANNEX III

Antenna gain toward the horizon for earth stations operating to geostationary space stations

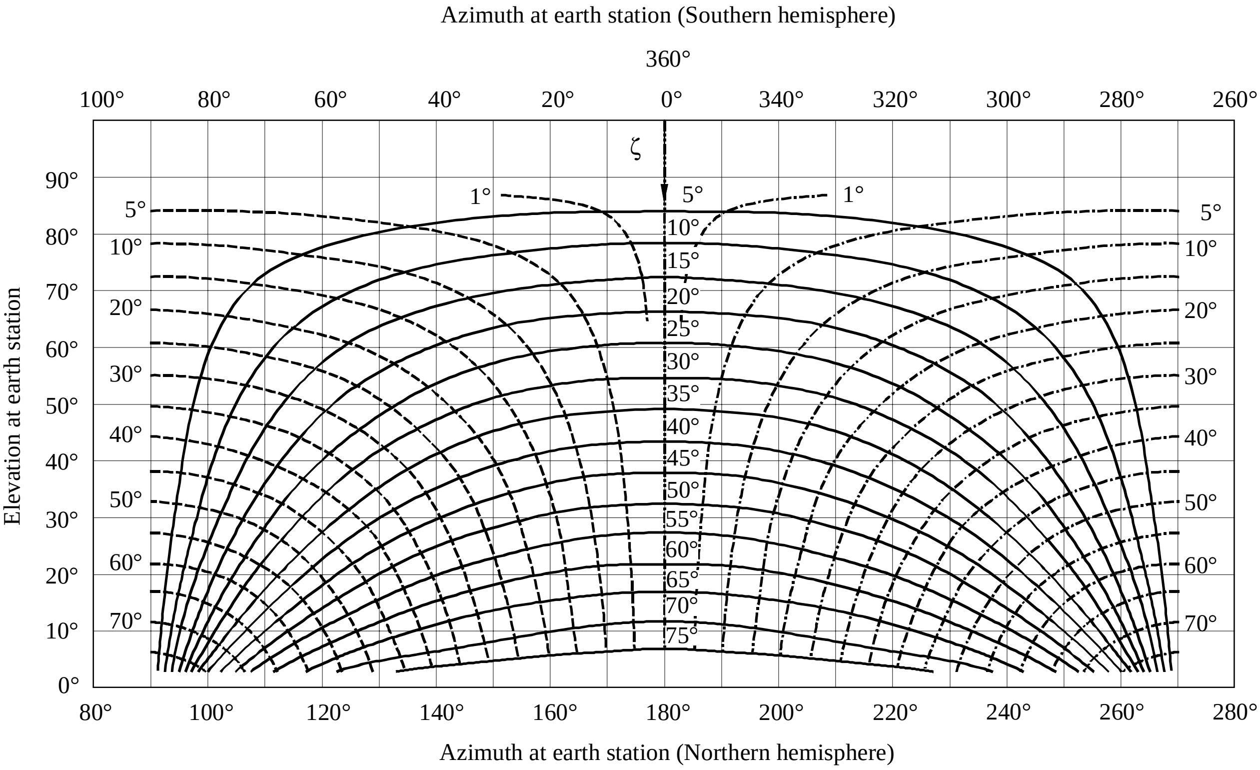
1 General

The gain component of the earth station antenna in the direction of the physical horizon around an earth station is a function of the angular separation between the antenna main beam axis and the horizon in the direction under consideration. When the earth station is used to transmit to a space station in a slightly inclined orbit, all possible pointing directions of the antenna main beam axis need to be considered. For earth station coordination, knowledge of $\varphi(\alpha)$, the minimum possible value of the angular separation that will occur during the operation of the space station, is required for each azimuth.

When a geostationary space station maintains its location close to its nominal orbital position, the earth station's main beam axis elevation angle ε_S and azimuth angle α_S to the space station from the earth station's latitude ζ are uniquely related. Figure III-1 shows the possible location arcs of positions of a space station on the geostationary orbit in a rectangular azimuth/elevation plot. It shows arcs corresponding to a set of earth station latitudes and the intersecting arcs correspond to points on the orbit with a fixed difference in longitude east or west of the earth station.

FIGURE II-1

Position arcs of geostationary satellites



——— Arc of geostationary-satellite orbit visible from earth station at terrestrial latitude ζ

Difference in longitude between the earth station and the sub-satellite point:

- - - - Satellite longitude E of earth station longitude

-·-·-·- Satellite longitude W of earth station longitude

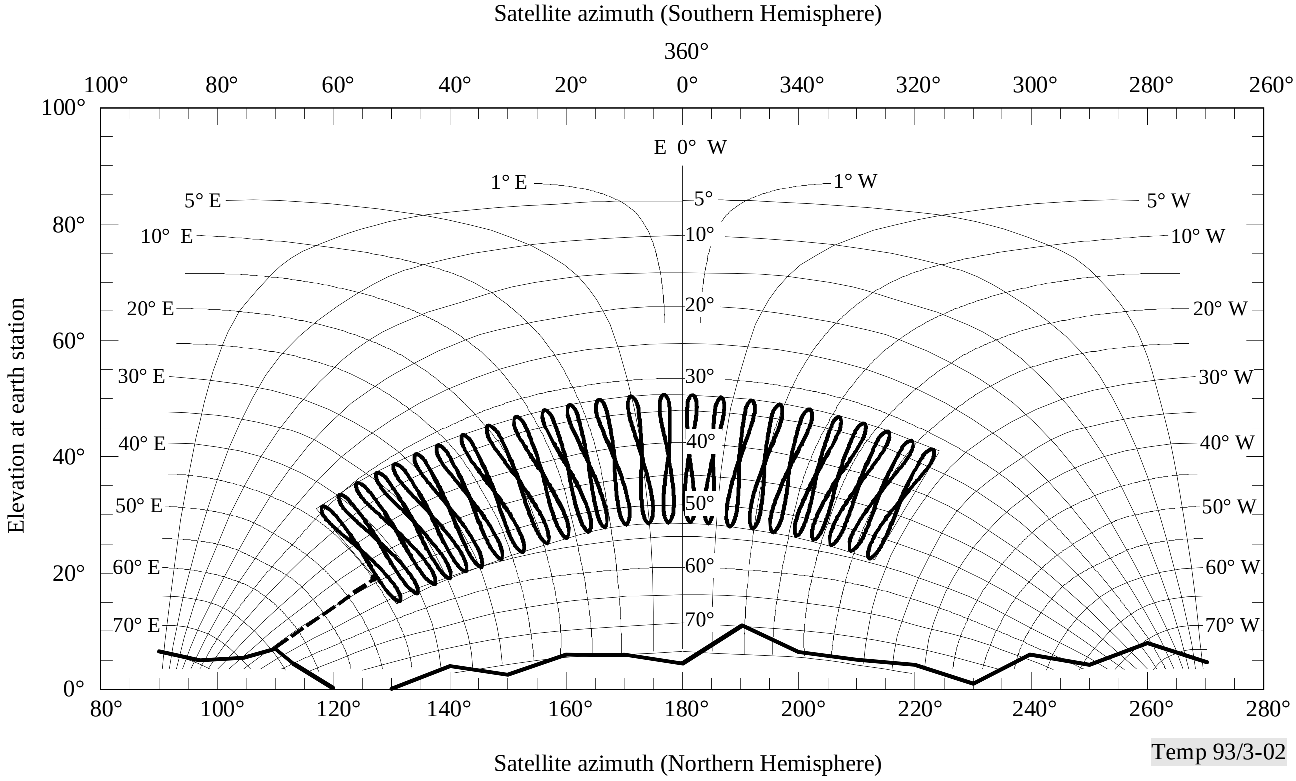
-··-··- Satellite longitude equal to the earth station longitude

APS07/07-II-1

When the north/south station-keeping of a geostationary satellite is relaxed, the orbit of the satellite becomes inclined with an inclination that increases gradually with time. As viewed from the earth, the position of the satellite traces a figure eight during each 24-hour period. Figure III-2 shows the variations in the trajectories of a set of satellites, each with 10° inclination, spaced by 3° along the geostationary orbit from 28° W to 44° E with respect to an earth station at 43° N longitude. Figure III-2 also shows, with a dashed curve, the great-circle arc corresponding to the minimum off-axis angle φ(α) between this envelope and the horizon profile at an azimuth of 110°.

FIGURE III-2

Position arcs of geostationary satellites with horizon and the arc from the horizon at azimuth 110° to the envelope of satellites with 10° inclination on the geostationary orbital arc from 28° W to 44° E of an earth station at 43° N latitude



For a transmitting earth station operating in a frequency band that is also allocated for bidirectional use by receiving earth stations operating to geostationary space stations, refer to § 1.1 of Annex V.

2 Determination of the angular separation φ(α)

For the determination of the off-axis angle φ(α), two cases are distinguished. These depend on whether or not the earth station will operate to a space station in a slightly inclined orbit. The following equations may be used both of these cases:

$$\psi_s(i, \delta) = \text{arc cos } (\sin \zeta \sin i + \cos \zeta \cos i \cos \delta) \qquad \text{(III-1)}$$

$$\varepsilon_S(i,\delta) = \arcsin\left[\frac{K\cos\psi_S(i,\delta) - 1}{\left(1 + K^2 - 2K\cos\psi_S(i,\delta)\right)^{1/2}}\right] \qquad \text{(III-2)}$$

$$\alpha'_{os}(i,\delta) = \arccos\left[\frac{\sin i - \cos\psi_s \sin\zeta}{\sin\psi_s \cos\zeta}\right] \tag{III-3}$$

$\alpha_s(i, \delta) = \alpha_{os}(i, \delta)$ for a space station located east of the earth station ($\delta \geq 0$) (III-4)

$\alpha_s(i, \delta) = 360° - \alpha_{os}(i, \delta)$ for a space station located west of the earth station ($\delta \leq 0$) (III-5)

$\varphi(\alpha, i, \delta) = \arccos\,[\cos \varepsilon_h(\alpha) \cos \varepsilon_s(i, \delta) \cos (\alpha - \alpha_s(i, \delta)) + \sin \varepsilon_h(\alpha) \sin \varepsilon_s(i, \delta)]$ (III-6)

where

ζ: latitude of the earth station (positive for north; negative for south)

δ: difference in longitude from the earth station to a space station

i: latitude of a sub-satellite point (positive for north; negative for south)

$\psi_s(i, \delta)$: great-circle arc between the earth station and a sub-satellite point

$\alpha_s(i, \delta)$: space station azimuth as seen from the earth station

$\varepsilon_s(i, \delta)$: space station elevation angle as seen from the earth station

$\varphi(\alpha, i, \delta)$: angle between the main beam and the horizon direction corresponding to the azimuth (α) under consideration when the main beam is steered towards a space station with a sub-satellite point at latitude i and longitude difference δ

α: azimuth of the direction under consideration

ε_h: elevation angle of the horizon at the azimuth, α under consideration

$\varphi(\alpha)$: angle to be used for horizon gain calculation at the azimuth under consideration, α

K: orbit radius/earth radius, which for the geostationary orbit is assumed to be 6.62.

All arcs mentioned above are in degrees.

Case 1: **Single space station, no orbital inclination**

For a space station operating with no orbital inclination at an orbital position with difference in longitude δ_0, equations (III-1) to (III-6) may be applied directly using $i = 0$ to determine $\varphi(\alpha)$ for each azimuth α. Thus:

$$\varphi(\alpha) = \varphi(\alpha, 0, \delta_0) \tag{III-7}$$

where

δ_0: longitude difference from the earth station to the space station.

Case 2: Single space station, in a slightly inclined orbit

For a space station operating in a slightly inclined orbit on a portion of the geostationary arc with nominal longitude difference of δ_0, the maximum orbital inclination over its lifetime, i_s, must be considered. Equations (III-1) to (III-6) may be applied to develop the minimum off-axis angle to each of four arcs in azimuth/elevation that bound the trajectory of the space station in angle and elevation. The bounding arcs correspond to the maximum and minimum latitudes of the sub-satellite points and the extremes of the difference in longitude between the earth and space stations when the space station is operating at its maximum inclination.

The determination of the minimum off-axis angles in equations (III-8), (III-9), (III-10), (III-11) and (III-12) may be made by taking increments along a bounding contour. The step size in inclination i or longitude δ should be between 0.5° and 1.0° and the end points of the respective ranges should be included in the calculation.

The horizon profile $\varepsilon_h(\alpha)$ used in the determination of $\varphi(\alpha)$ is specified at increments in azimuth α that do not exceed 5°.

Thus:

$$\varphi(\alpha) = \min_{n = 1 \text{ to } 4} \varphi_n(\alpha) \tag{III-8}$$

with:

$$\varphi_1(\alpha) = \min \varphi(\alpha, -i_s, \delta) \quad \delta_0 - \delta_s \le \delta \le \delta_0 + \delta_s \tag{III-9}$$

$$\varphi_2(\alpha) = \min \varphi(\alpha, i_s, \delta) \quad \delta_0 - \delta_s \le \delta \le \delta_0 + \delta_s \tag{III-10}$$

$$\varphi_3(\alpha) = \min \varphi(\alpha, i, \delta_0 - \delta_s) \quad -i_s \le i \le i_s \tag{III-11}$$

$$\varphi_4(\alpha) = \min \varphi(\alpha, -i_s, \delta_0 + \delta_s) \quad -i_s \le i \le i_s \tag{III-12}$$

$$\delta_s = (i_s / 15)^2 \tag{III-13}$$

where

i_s: maximum operational inclination angle of the satellite orbit

δ_s: maximum longitude change from nominal value of the sub-satellite point of a satellite with orbital inclination i_s.

3 Determination of antenna gain

The relationship $\varphi(\alpha)$ is used to derive a function for the horizon antenna gain, G (dB) as a function of the azimuth α, by using the actual earth station antenna pattern, or a formula giving a good approximation. For example, in cases where the ratio between the antenna diameter and the wavelength is equal to or greater than 35, the following equation is used:

$$G(\varphi) = \begin{cases} G_{amax} - 2.5 \times 10^{-3}\left(\dfrac{D}{\lambda}\varphi\right)^2 & \text{for } 0 < \varphi < \varphi_m \\ G_1 & \text{for } \varphi_m \le \varphi < \varphi_r \\ 29 - 25\log\varphi & \text{for } \varphi_r \le \varphi < 36^\circ \\ -10 & \text{for } 36^\circ \le \varphi \le 180^\circ \end{cases} \tag{III-14}$$

$$G_1 = \begin{cases} -1 + 15\log\left(D/\lambda\right) & \text{dBi} \quad \text{for } D/\lambda \ge 100 \\ -21 + 25\log\left(D/\lambda\right) & \text{dBi} \quad \text{for } 35 \le D/\lambda < 100 \end{cases}$$

$$\varphi_m = \frac{20\lambda}{D}\sqrt{G_{amax} - G_1} \qquad \text{degrees}$$

$$\varphi_r = \begin{cases} 15.85\left(D/\lambda\right)^{-0.6} & \text{degrees} \qquad \text{for } D/\lambda \geq 100 \\ 100\left(\lambda/D\right) & \text{degrees} \qquad \text{for } 35 \leq D/\lambda < 100 \end{cases}$$

Where a better representation of the actual antenna pattern is available, it may be used.

In cases where D/λ is not given, it may be estimated from the expression:

$$20\log\frac{D}{\lambda} \approx G_{amax} - 7.7$$

where

G_{amax}: main beam axis antenna gain (dBi).

D: is the antenna diameter and λ is the wavelength: both expressed in metres.

G_1: gain of the first side lobe

ANNEX IV

Antenna gain toward the horizon for earth stations operating to non-geostationary space stations

This Annex presents methods which may be used to determine the antenna gain towards the horizon for earth stations operating to non-geostationary satellites using the method described in § 2.2 of the main body of the Appendix.

1 Determination of the horizon antenna gain

In its simplest implementation, this method depends on the minimum elevation angle of the beam axis of the earth station antenna (ε_{sys}), which is a system parameter that has the same value on all azimuths from the earth station. If the horizon elevation angle at an azimuth under consideration is ε_h degrees, the minimum separation angle from the horizon at this azimuth to any possible pointing angle for the main beam axis of the antenna (φ_{min}) is equal to the difference between these two angles ($\varepsilon_{sys} - \varepsilon_h$), but it is not less than zero degrees. The maximum separation angle from the horizon at this azimuth to any possible pointing angle for the main beam axis of the antenna (φ_{max}) is equal to the difference between the sum of these two angles and 180 degrees ($180 - \varepsilon_{sys} - \varepsilon_h$). The maximum and minimum values of horizon gain for the azimuth under consideration are obtained from the gain pattern of the earth station antenna at these off-axis angles. Where no pattern is available the pattern of § 3 of Appendix III may be used.

Additional constraints may be included in the determination of the maximum and minimum values of horizon antenna gain where an earth station operates with a constellation of non-geostationary satellites that are not in near-polar orbit. In this case, depending on the latitude of the earth station, there may be portions of the hemisphere above the horizontal plane at the earth station in which no satellite will appear. To include these visibility limitations within this method, it is first necessary to determine, for a closely spaced set of azimuth angles around the earth station, the minimum elevation angle at which a satellite may be visible. This minimum satellite visibility elevation angle (ε_v) may be determined from consideration of the visibility of the edge of the shell formed by all possible orbits having the orbital inclination and altitude of the satellites in the constellation.

The lowest elevation angle toward which the main-beam axis of the earth station antenna will point on any azimuth is the minimum composite elevation angle (ε_c), which is equal to the greater of the minimum satellite visibility elevation angle (ε_v) and the minimum elevation angle of the earth station (ε_{sys}). After the minimum composite elevation angle has been determined for all azimuths by the procedure of § 1.1 of this Annex, the resulting profile of the minimum composite elevation angles can be used, in the procedure of § 1.2 of this Annex, to determine the maximum and minimum values of horizon gain at any azimuth.

1.1 Determination of satellite visibility limits

The visibility limits of a constellation of satellites can be determined from the inclination angle of the most inclined satellite and the altitude of the lowest satellite in the constellation. For this determination, six cases may be distinguished, but not all of these may be applicable for a given constellation and a given earth station latitude. The azimuth and the corresponding lower limit on the elevation angle are developed by a parametric method using a set of points on the edge of the orbital shell of the constellation. The approach is to develop this relationship for azimuths to the east of a station in the northern hemisphere. Elevation angles for azimuths to the west of the station and for all azimuths for stations in the southern hemisphere are obtained by symmetry. The following equations, which are applicable to circular orbits only, may be used for the complete determination of the horizon antenna gain in all practical cases:

$$\psi(\delta) = \text{arc cos } (\sin \zeta \sin i + \cos \zeta \cos i \cos \delta) \qquad \text{(IV-1)}$$

$$\varepsilon_V(\delta) = \arcsin\left[\frac{K_1 \cos[\psi(\delta)] - 1}{\left(1 + K_1^2 - 2K_1 \cos[\psi(\delta)]\right)^{1/2}}\right] \qquad \text{(IV-2)}$$

$$\alpha_0(\delta) = \arccos\left[\frac{\sin i - \cos[\psi(\delta)] \ \sin\zeta}{\sin[\psi(\delta)] \ \cos\zeta}\right] \qquad \text{(IV-3)}$$

with

$$\alpha(\delta) = \begin{cases} \alpha_0(\delta) \quad \text{and} & \\ 360 - \alpha_0(\delta) & \text{for earth stations north of the Equator} \\ 180 - \alpha_0(\delta) \quad \text{and} & \\ 180 + \alpha_0(\delta) & \text{for earth stations south of the Equator} \end{cases} \qquad \text{(IV-4)}$$

where

- i: the orbital inclination of the satellites in the constellation assumed to be positive and between 0° and 90°
- ζ: modulus of the latitude of the earth station
- δ: difference in longitude from the earth station to a point on the edge of the orbital shell of the constellation
- $\psi(\delta)$: great-circle arc between the earth station and a point on the surface of the earth directly below the point on the edge of the orbital shell of the constellation
- $\alpha(\delta)$: azimuth from the earth station to a point on the edge of the orbital shell
- $\alpha_0(\delta)$: the principle azimuth, an azimuth between 0 and 180 degrees, from an earth station north of the Equator to a point on the edge of the orbital shell
- $\varepsilon_V(\delta)$: elevation angle from the earth station to a point on the edge of the orbital shell
- K_1: orbit radius/earth radius for the lowest altitude satellite in the constellation (earth radius = 6 378.14 km)

$$\psi_m = \arccos(1/K_1)$$

All arcs mentioned above are in degrees.

For any latitude on the surface of the earth, the azimuth for which the minimum elevation angle to a satellite can be greater than zero, and the corresponding elevation angles, may be determined by implementing the calculations under the following case(s). No more than two of these cases will be applicable for any latitude. For situations not specifically addressed in the following cases, no satellite is visible at elevation angles at or below 90° on any azimuth.

Case 1: For: $\zeta \le i - \psi_m$

For this case a satellite may be visible to the horizon for all azimuths about the earth station ($\varepsilon_v = 0$).

Case 2: For: $i - \psi_m < \zeta \le \arcsin(\sin i \cos \psi_m)$

For this case the azimuth angles and elevation are developed parametrically by choosing a set of values of δ, uniformly spaced on the interval 0 to δ_1, and applying equations IV-1 to IV-4. For this purpose the spacing between values is not to exceed 1.0 degree, and the endpoints are to be included.

$$\delta_1 = \arccos\left[\frac{\cos\psi_m - \sin\zeta \sin i}{\cos\zeta \cos i}\right]$$

At any principal azimuth ($\alpha_0(\delta)$) that is not included in the set, the minimum elevation angle is zero ($\varepsilon_v = 0$), except for azimuths where Case 6 additionally applies.

Case 3: For: $\arcsin(\sin i \cos \psi_m) < \zeta < i$, and $\zeta < 180 - \psi_m - i$

For this case the azimuth angles and elevation are developed parametrically by choosing a set of values of δ, uniformly spaced on the interval 0 to δ_2, and applying equations IV-1 to IV-4. For this purpose the spacing between values is not to exceed 1.0 degree, and the endpoints are to be included.

$$\delta_2 = 2\arctan\left[\frac{\sqrt{\sin^2\psi_m - \cos^2 i \sin^2 \delta_i}}{\sin\zeta \cos i \sin\delta i}\right] - \delta i$$

At any principal azimuth ($\alpha_0(\delta)$) that is not included in the set, the minimum elevation angle is zero ($\varepsilon_v = 0$), except for azimuths where Case 6 additionally applies.

Case 4: For: $i \le \zeta < i + \psi_m$, and $\zeta < 180 - i - \psi_m$

For this case, the minimum elevation angle is given explicitly in terms of the principal azimuth angle α_0 as follows:

$$\varepsilon_v = \begin{cases} 90 & \text{for} \quad 0 \le \alpha_0 < \alpha_2 \\ 0 & \text{for} \quad \alpha_2 \le \alpha_0 \le 180 \end{cases}$$

where

$$\alpha_2 = \arccos\left[\frac{\sin i - \cos\psi_m \sin\zeta}{\sin\psi_m \cos\zeta}\right]$$

Note that a minimum elevation angle of 90 degrees in this formulation indicates that no satellite is visible at elevation angles at or below 90 degrees on these azimuths, furthermore, within the range of principal azimuths where the minimum elevation angle is zero, Case 6 may additionally apply.

Case 5: For $180 - i - \psi_m \le \zeta \le 90$

For this case, a satellite may be visible to the horizon for all azimuths about the earth station $(\varepsilon_v = 0)$.

Case 6: For $\zeta < \psi_m - i$

This case may occur additionally with Case 2, Case 3 or Case 4 and a satellite may be visible only above a minimum elevation angle for other principal azimuths.

For this case the other principal azimuths and the corresponding elevation angles are developed parametrically by choosing a set of values δ, uniformly spaced on the interval 0 to δ_3, and applying equations (IV-1) to (IV-4) with i replaced by –i. For this purpose the spacing between values is not to exceed 1.0 degree and the end points are to be included.

$$\delta_3 = \arccos\left[\frac{\cos\psi_m + \sin\zeta \sin i}{\cos\zeta \cos i}\right]$$

1.2 Determination of minimum and maximum horizon gain from the minimum visible elevation angle profile

The horizon gain of the earth station antenna is determined from the profile of values of the minimum composite elevation angle (ε_c). At any azimuth the minimum composite elevation angle is the greater of the minimum satellite visibility elevation angle at that azimuth(ε_v) and the minimum elevation angle for the earth station (ε_{sys}). The following procedure may be used to determine the maximum and minimum values of horizon antenna gain for each azimuth under consideration.

The following equation may be used to determine the angular separation from the horizon profile, at an azimuth angle α and horizon elevation angle ε_h, to a point on the profile of the minimum composite elevation angle, where the minimum composite elevation angle is ε_c at an azimuth angle of α_c:

$$\varphi(\alpha, \alpha_c) = \arccos\left[\sin \varepsilon_h(\alpha) \sin(\varepsilon_c(\alpha_c)) + \cos \varepsilon_h(\alpha) \cos(\varepsilon_c(\alpha_c)) \cos(\alpha - \alpha_c)\right] \qquad \text{(IV-5)}$$

where

- α: azimuth of the direction under consideration
- $\varepsilon_h(\alpha)$: elevation angle of the horizon at the azimuth, α, under consideration
- $\varepsilon_c(\alpha_c)$: minimum composite elevation angle at the azimuth, α_c
- α_c: azimuth corresponding to ε_c.

The minimum value of the separation angle φ_{min}, for the azimuth under consideration, is determined by finding the minimum value of $\varphi(\alpha, \alpha_c)$ for any azimuth α_c, and the maximum value, φ_{max}, is determined by finding the maximum value of $\varphi(\alpha, \alpha_c)$ for any azimuth α_c. The azimuth angles (α) are usually taken in increments of 5 degrees; however, to accurately determine the minimum separation angle, the values of the minimum composite elevation angle, ε_c, needs to be determined for a spacing of 1 degree or less in the azimuth α_c. Where the procedure in § 1.1 of this Annex do not provide a profile of minimum composite elevation angle with a close enough spacing in azimuth angles, linear interpolation may be used to develop the necessary intermediate values. The maximum and minimum horizon antenna gains, G_{max} and G_{min}, to be used in the equations of § 2.2 of the main body of the Appendix for the azimuth under consideration, are obtained by applying the off-axis angles, φ_{min} and φ_{max}, respectively, in the earth station antenna pattern. If the earth station antenna pattern is not known then the antenna pattern in § 3 of Annex III is used. In many cases, φ_{max} will be large enough on all azimuths so that G_{min} will be equal to the minimum gain of the antenna pattern at all azimuths.

ANNEX V

Determination of the coordination area for a transmitting earth station with respect to receiving earth stations operating to geostationary space stations in bidirectionally allocated frequency bands

1 Introduction

The propagation mode (1) coordination area of a transmitting earth station, with respect to unknown receiving earth stations that operate to geostationary space stations, requires the determination of the horizon gain of the antenna of the receiving earth station at each azimuth of the transmitting earth station. Different methods then need to be applied to determine the coordination area of the coordinating earth station depending on whether it operates to geostationary or non-geostationary space stations. When both the coordinating earth station and the unknown receiving earth stations operate to geostationary space stations, it is also necessary to determine a propagation mode (2) coordination contour.

The coordination area of a transmitting earth station, with respect to unknown receiving earth stations that operate to non-geostationary space stations, can be determined by minor modifications to the methods applicable to the determination of coordination area of transmitting earth stations with respect to terrestrial stations. (See § 3.2.1 and 3.2.3 of the main body of the Appendix.)

2 Determination of the bidirectional coordination contour for propagation mode (1)

For a transmitting earth station operating in a frequency band that is also allocated for bidirectional use by receiving earth stations operating to geostationary space stations, further development of the procedures in Annex III is needed. It is necessary to determine the horizon gain of the unknown receiving earth station, the horizon gain to be used at each azimuth at the coordinating (transmitting) earth station, for the determination of the bidirectional coordination area.

2.1 Calculation of horizon gain for unknown receiving earth stations operating to geostationary space stations

The value of G_r , the horizon gain of the receiving earth station, for each azimuth (α) at the transmitting earth station is found by the following steps:

1) The receiving earth station may be operating to any satellite in the geostationary orbit above a minimum elevation angle, (ε_s) contained in Table 3 to Annex VII. The maximum difference in longitude (δ_b in degrees) between the receiving earth station and its associated space station occurs at this minimum elevation angle (ε_s) and is given by:

$$\delta_b = \arccos\left(\frac{\sin\left(\varepsilon_s + \arcsin\left(\frac{\cos(\varepsilon_s)}{K}\right)\right)}{\cos(\zeta)}\right) \qquad \text{(V-1)}$$

where

ζ : is the latitude of the receiving earth station, which is assumed to be the same as the transmitting earth station, and

K is the ratio of the radius of the satellite orbit to the radius of the earth and equals 6.62.

2) For each azimuth (α) at the transmitting earth station:

a) determine the azimuth α_r from the receiving earth station to the transmitting earth station:

$$\alpha_r = \alpha + 180° \qquad \text{for } \alpha < 180$$

$$\alpha_r = \alpha - 180° \qquad \text{for } \alpha \geq 180$$

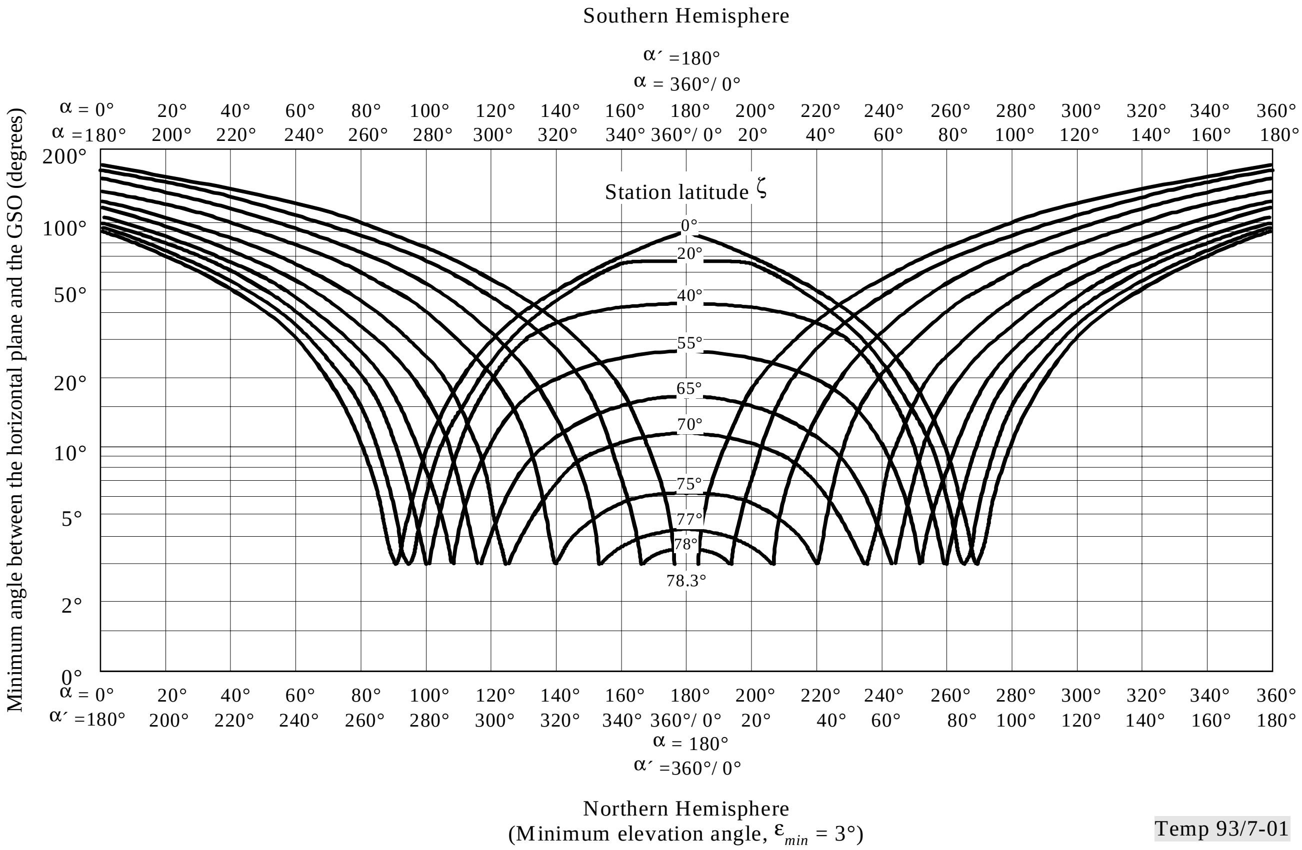
b) for each azimuth, α_r determine the minimum angular separation, $\varphi(\alpha_r)$ between the receiving earth station main beam axis and the horizon at this azimuth using Case 1 in § 2 of Annex III. For this evaluation $\varphi(\alpha_r)$ is the minimum value of $\varphi(\alpha_r, 0, \delta_0)$ where the values of δ_0 are between $-\delta_b$ and $+\delta_b$ in steps of 1 degree or less making sure to include the end points.

The minimum angular separation, $\varphi(\alpha_r)$, may be used with the gain pattern in § 3 of Annex III to determine the horizon gain for this azimuth (α), unless a different gain pattern is referenced in Table 3 of Annex VII.

Figure V-1 shows plots of the minimum angular separation between the horizon at zero degrees elevation on an azimuth α_r and a satellite on the geostationary orbit at an elevation above 3 degrees. Plots are shown for a set of values of the station latitude (ζ), which is assumed to be the same for both transmitting and receiving earth stations. Figure V-1 also provides a scale showing the corresponding azimuth (α) of the transmitting earth station.

Figure V-1

Illustration of minimum angular distance between points on the geostationary-satellite orbit (GSO) and the horizontal plane



3 Determination of the bidirectional rain scatter contour

The procedure for the determination of the bidirectional rain scatter area, as described in § 3.1.2 of the main body of the Appendix, is as follows:

The horizontal distance d_t (km) from the coordinating earth station to the point at which the main beam axis attains the rain height h_R is calculated by:

$$d_t = 8\,500\left(\sqrt{\tan^2 \varepsilon_s + h_R / 4\,250} - \tan \varepsilon_s\right) \text{ km} \qquad \text{(VI-2)}$$

where the rain height, h_R, can be determined from equations (II-13) or (II-14) in Annex II.

The maximum calculation distance, d_{emax}, to be used in the determination of the propagation mode (2) contour, for the case of a coordinating earth station operating in bidirectionally allocated frequency bands, is dependent on the rain height. It is the greater distance determined from:

$$d_{emax} = 130.4\sqrt{h_R} \text{ km or } d_{min}$$

where the minimum coordination distance, d_{min}, is given in § 4.2 of the main body of the Appendix.

The point, at the distance d_s from the earth station, on the azimuth α_s of the coordinating earth station's main beam axis, is the geographic point immediately below the main beam axis intersection with the rain height, and is the reference point from which the maximum calculation distance d_{emax} is measured (see Figure V-2).

If the maximum calculation distance, d_{emax}, is greater than the minimum coordination distance, d_{min}, then, calculate the maximum latitude at which a receiving earth station may operate to a geostationary satellite with a minimum elevation angle ε_s:

$$\zeta_{\max} = \arccos\left[\frac{\cos(\varepsilon_s)}{K}\right] - \varepsilon_s \qquad \text{(VI-3)}$$

where

ε_s: is given in Table 3 of Annex VII and

K: is the ratio of the radius of the satellite orbit to the radius of the earth and equals 6.62.

If the coordinating earth station latitude in the northern hemisphere is greater than ζ_{max}, or if the coordinating earth station latitude in the southern hemisphere is less than $-\zeta_{max}$ or –71°, then the rain scatter contour is a circle of radius d_{min}, centred on the transmitting earth station.

For all other cases, the coordination area is developed by the following procedure:

Step 1: The unknown receiving earth station is assumed to be operating to a satellite at the minimum elevation angle ε_s. It is also assumed that the receiving earth station is relatively close to the coordinating earth station in geometric terms hence, a plane geometry approximation can be applied within the coordination area. If the receiving earth station's main beam axis passes through the intersection of the coordinating earth station's main beam axis with the rain height, the azimuths from the point on the ground, immediately below this intersection, to the possible locations of a receiving earth station are given by:

$$\alpha_{w1} = \arccos\left[\frac{\tan\zeta}{\tan\zeta_{\max}}\right]$$

and

$$\alpha_{w2} = 360 - \alpha_{w1}$$

where

ζ is the latitude of the transmitting earth station.

Step 2: Mark on a map of an appropriate scale the coordinating earth station's location and draw from this location a line of distance, d_s, along the azimuth, α_s, to the point below the coordinating earth station's main beam axis intersection with the rain height.

Step 3: From the main beam axis intersection point in step 2, mark on the map the distance, d_{emax}, along the two azimuths, α_{w2} and α_{w1}, and on each azimuth at the distance, d_{emax}, draw two equal distance arcs of width 3° clockwise and counter-clockwise. The two arcs, each having a total width of 6°, are the first boundary elements of the bidirectional rain scatter area.

Step 4: Mark a circle of radius equal to the minimum coordination distance, d_{min}, around the coordinating earth station's location, and then draw straight lines from the northern edges of the two arc segments tangential to the northern rim of the circle, and from the southern edges of the two arc segments tangential to the southern rim of the circle.

The area bounded by the two 6° wide arcs, the four straight lines, and the circular sections (of which there is always at least one) between the two northern and the two southern tangent points with the straight lines, constitutes the bidirectional rain scatter area.

Figure V-2 illustrates the construction of the bidirectional rain scatter area for a coordinating earth station. (The resulting rain scatter area contains the possible loci of all receiving earth station locations from which a beam path towards the geostationary-satellite orbit will intersect the main beam of the transmitting earth station antenna.)

ANNEX VI

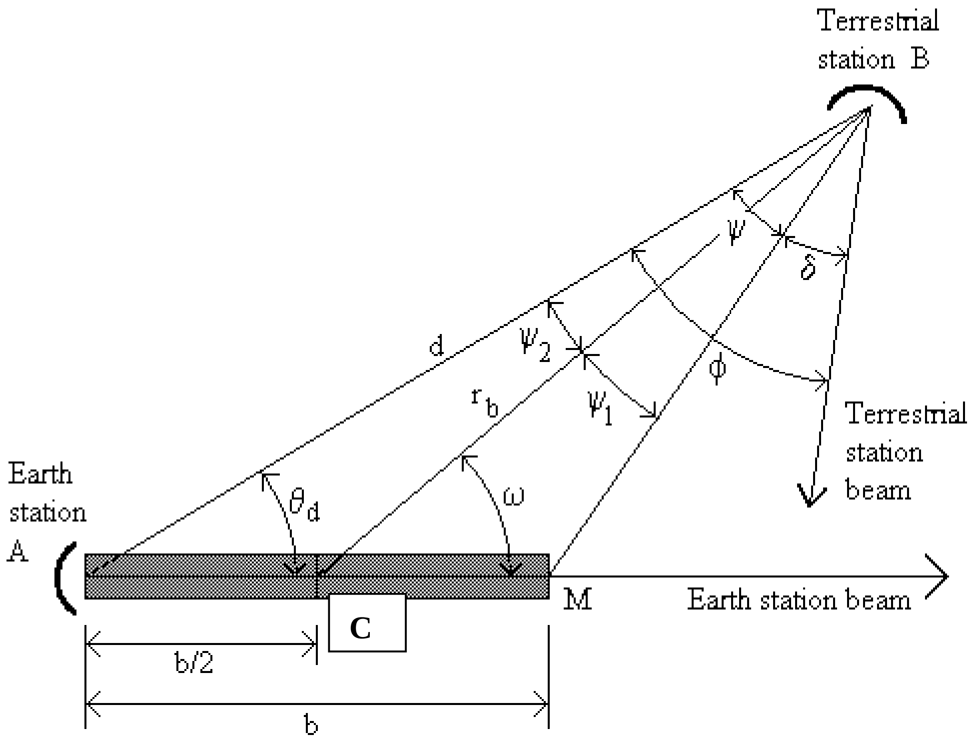
Determination of auxiliary contours for propagation mode (2)

1 Determination of auxiliary contours for propagation mode (2)

Propagation mode (2) auxiliary contours allow the azimuthal offset of a terrestrial station antenna beam from the coordinating earth station's location to be taken into consideration. Figure VI-1 shows the hydrometeor scatter region projected on to the horizontal plane. In this figure the earth station and the terrestrial station are located at the points A and B respectively, where the terrestrial station is on a radial defined by the angle ω from the point C at the centre of the propagation mode (2) main, or supplementary, contour. Point C is also the centre of the auxiliary contour.

FIGURE VI-1

Propagation geometry in the horizontal plane



The shaded area in Figure VI-1 represents the critical region, along the earth station's main beam axis, between the earth station and the rain height. Within this critical region a common volume can be formed between the earth station beam and the beam of any terrestrial stations within the propagation mode (2) main, or supplementary, contour. This critical region's length is *b* and its maximum horizontal extent is at point M. Intersection of this critical region by the terrestrial station main beam axis, would result in significant hydrometeor scatter interference via main lobe to main lobe coupling.

For a given point within the propagation mode (2) main, or supplementary, contour, the angle subtended by the critical region is termed the critical angle, ψ. The protection angle, υ, represents the angle of the terrestrial station main beam axis away from the critical region. The beam avoidance angle between the terrestrial station's main beam axis and the earth station's location is φ. It is the sum of the two angles ψ and υ and it is this quantity that has a fixed value for a specific auxiliary contour. Each auxiliary contour is generated by varying the angle, ω, and deriving the distance (r_b) from point C to the auxiliary contour. As the angle ω increases from 0° to 360°, the angles ψ and υ change, but their sum remains the same.

The algorithm in § 2 of this Annex can be used to calculate the auxiliary propagation mode (2) contour for a given value of beam avoidance angle φ.

The method is based on iteratively decrementing the distance, r_b, between terrestrial station and the centre of the common volume, and starting at the main contour distance d_r, until either the shortest value of r_b is found for which the required minimum loss is achieved, or the minimum coordination distance is reached. For each value of r_b the critical angle ψ is determined and then the protection angle υ is calculated. The terrestrial station antenna gain corresponding to υ and the current distance r_b are then used in equation (II-21) to obtain the propagation mode (2) path loss.

The above process is repeated for each angle ω, to generate a complete auxiliary contour for a given value of beam avoidance angle φ. For some combinations of beam avoidance angle and angle ω an auxiliary contour may coincide with the main, or supplementary, propagation mode (2) contour.

2 The step-by-step algorithm

Auxiliary propagation mode (2) contours are constructed by calculating distances along radials from the centre of the circular mode (2) main, or supplementary, contour, which is the point C, at the distance b/2 from the earth station along the azimuth of its main beam axis. The distance b/2 is equal to Δd, where Δd is given by equation (II-23), see Annex II.

For the selected value of beam avoidance angle, φ, generate the auxiliary contour for values of angle, ω, ranging from 0° to 180° in steps of 1° as follows:

a) Set r_b to the main, or supplementary, mode (2) contour distance d_r calculated as described in § 3.1 of Annex II.

b) Compute ψ from:

$$\psi_1 = \text{arc tan}\left(\frac{b\sin\omega}{2r_b - b\cos\omega}\right) \quad \text{(VI-1)}$$

$$\psi_2 = \text{arc tan}\left(\frac{b\sin\omega}{2r_b + b\cos\omega}\right) \quad \text{(VI-2)}$$

$$\psi = \psi_1 + \psi_2 \quad \text{(VI-3)}$$

c) If $\psi > \varphi$ then the auxiliary mode (2) contour coincides with the main or supplementary mode (2) contour for the current value of ω, and the calculation for that value of ω is completed, and go to step J. Otherwise proceed through the following steps d) to i) until one of the terminating conditions described in step f) and step i) are satisfied.

d) Decrement r_b by subtracting 0.2 km from its value.

e) Recalculate the critical angle ψ using equations (VI-1), (VI-2) and (VI-3).

f) If (0.5 b sin ω/sin ψ_2) < d_{min} the auxiliary mode (2) contour coincides with the minimum coordination distance d_{min} and the calculation for the current value of ω is completed and go to step J. Otherwise proceed to step g).

g) Compute the protection angle $\upsilon = \varphi - \psi$.

h) Calculate $G(\upsilon)$ the terrestrial station antenna gain at the angle υ relative to the beam axis using the reference antenna pattern given in this Annex.

i) In equation (II-21) use the gain calculated in step h) in place of G_x and the current value of r_b in place of r_i and calculate the corresponding propagation mode (2) path loss L_r. If $L_r < L(p)$ then increment r_b by adding 0.2 km to its value and take this as the distance for the current radial. Otherwise repeat from step d).

j) Once the value of r_b has been found for the current value of angle ω, calculate the angle θ_d from the location of the earth station, and if appropriate the distance, d, to that contour point using:

$$d = 0.5\ b \sin \omega / \sin \psi_2 \qquad \text{(VI-4)}$$

$$\theta_d = \omega - \psi_2 \qquad \text{(VI-5)}$$

An auxiliary propagation mode (2) contour is symmetrical about the earth station main beam axis. Thus values of d and θ_d corresponding to the values of ω from 181° to 359° can be found by noting that results for a given value of ω are the same as for ($-\omega$) or (360°$-\omega$).

The step size for incrementing r_b used above, 0.2 km, is suitable for most situations. It controls the granularity of the result when viewed as a set of r_b values. For low values of earth station beam elevation the granularity becomes more noticeable in the values of d and θ_d, and a smaller step size may be used.

3 Reference radiation patterns for line-of-sight radio-relay system antennas

The reference radiation pattern for line-of-sight radio-relay system antennas in this section is used for the unknown terrestrial station antenna in the propagation mode (2) contour calculations when the actual antenna pattern is not available. This antenna pattern can be used in the frequency range 1 000 MHz - 40.5 GHz to determine the main or supplementary contours, or for developing auxiliary contours.

a) In cases where the ratio between the antenna diameter and the wavelength is greater than 100, the following equation is used:

$$G(\varphi) = G_{amax} - 2.5 \times 10^{-3} \left(\frac{D}{\lambda}\varphi\right)^2 \quad \text{for} \quad 0 < \varphi < \varphi_m \qquad \text{(VI-13)}$$

$$G(\varphi) = G_1 \quad \text{for} \quad \varphi_m \leq \varphi < \varphi_r \qquad \text{(VI-14)}$$

$$G(\varphi) = 32 - 25 \log \varphi \quad \text{for} \quad \varphi_r \leq \varphi < 48° \qquad \text{(VI-15)}$$

$$G(\varphi) = -10 \quad \text{for} \quad 48° \leq \varphi \leq 180° \qquad \text{(VI-16)}$$

$$G_1 = 2 + 15 \log \frac{D}{\lambda} \qquad \text{(VI-17)}$$

$$\varphi_m = \frac{20\lambda}{D} \sqrt{G_{\mathrm{amax}} - G_1} \qquad \text{(VI-18)}$$

$$\varphi_r = 15.85 \left(\frac{D}{\lambda} \right)^{-0.6} \qquad \text{(VI-19)}$$

b) In cases where the ratio between the antenna diameter and the wavelength is less than or equal to 100, the following equation should be used:

$$G(\varphi) = G_{amax} - 2.5 \times 10^{-3} \left(\frac{D}{\lambda} \varphi \right)^2 \quad \text{for} \quad 0 < \varphi < \varphi_m \qquad \text{(VI-20)}$$

$$G(\varphi) = G_1 \quad \text{for} \quad \varphi_m \leq \varphi < 100 \frac{\lambda}{D} \qquad \text{(VI-21)}$$

$$G(\varphi) = 52 - 10 \log \frac{D}{\lambda} - 25 \log \varphi \quad \text{for} \quad 100 \frac{\lambda}{D} \leq \varphi < 48° \qquad \text{(VI-22)}$$

$$G(\varphi) = 10 - 10 \log \frac{D}{\lambda} \quad \text{for} \quad 48° \leq \varphi \leq 180° \qquad \text{(VI-23)}$$

c) In cases where only the maximum antenna gain is known, D/λ can be estimated from the following expression:

$$20 \log \frac{D}{\lambda} \approx G_{a\max} - 7.7 \qquad \text{(VI-24)}$$

where

G_{amax}: is the main beam axis antenna gain (dBi).

D: is the antenna diameter and λ is the wavelength: both expressed in metres.

G_1: is the gain of the first side lobe.

ANNEX VII

System parameters and predetermined coordination distances for determination of the coordination area around an earth station

1 System parameters introduction

Tables 1-3 contain the system parameter values required by the methods in the main body of the Appendix to determine the coordination area around a coordinating earth station in the space services when the band is shared with terrestrial radiocommunication services or other earth stations operating in the opposite direction of transmission.

Table 1 is limited to those system parameter values required for the case of a transmitting earth station sharing with terrestrial services; Table 2 is limited to those parameter values required for the case of a receiving earth station sharing with terrestrial services; Table 3 is limited to those parameter values required for the case of a coordinating transmitting earth station which is sharing in a bidirectionally allocated band with other earth stations operating in the opposite direction of transmission.

These system parameter Tables include primary allocations to the space and terrestrial services in Article S5 of the Radio Regulations in all bands between 100 MHz and 105 GHz. Some of the columns have incomplete information. In some cases, this is because there is no requirement to calculate coordination distances as pre-determined coordination distances apply. In other cases, the service allocations are new and the systems may not be introduced for some years. Hence, the system parameters are the subject of ongoing development within the ITU-R Study Groups.

Parameters specific to the coordinating earth station, are provided to the BR in the format specified in RR Appendix S4 as part of the notification and coordination processes.

The row in each Table entitled “method to be used” directs the user to the appropriate section of the main body of the Appendix which describes the methods to be followed for the determination of the coordination area.

Note that the earth station for which the coordination area is to be determined is identified by the service designation given in the first row of each Table.

When a supplementary contour is to be developed, for example for digital fixed systems, the necessary system parameters may be found in one of the adjacent columns in Tables 1, 2 and 3 of this annex. If no suitable system parameters are available then the value of the permissible interference power ($P_r(p)$) may be calculated using equation 1 of § 2.

2 Calculation of the permissible interference power of an interfering emission

Tables 1, 2 and 3 contain values for the parameters which are required for the calculation of the permissible interference power of the interfering emission (dBW), in the reference bandwidth, to be exceeded for no more than *p*% of the time at the receiving antenna terminal of a station subject to interference, from a single source of interference, using the general formula:

$$P_r(p) = 10 \log (k\, T_e\, B) + N_L + 10 \log (10^{M_S/10} - 1) - W \qquad \text{dBW} \qquad (1)$$

where

- k: Boltzmann's constant, 1.38×10^{-23} J/K
- T_e: the thermal noise temperature of the receiving system (K), at the terminal of the receiving antenna (see § 2.1 of this annex)
- N_L: link noise contribution (see § 2.2 of this annex)
- B: the reference bandwidth (Hz), i.e., the bandwidth in the receiving station that is subject to the interference and over which the power of the interfering emission can be averaged
- p: the percentage of the time during which the interference from one source may exceed the permissible interference power value; since the entries of interference are not likely to occur simultaneously: $p = p_0/n$
- p_0: the percentage of the time during which the interference from all sources may exceed the threshold value
- n: the number of equivalent equal level, equal probability entries of interference, assumed to be uncorrelated for small percentages of the time
- M_s: link performance margin (dB) (see § 2.3 of this annex)
- W: a thermal noise equivalence factor (dB) for interfering emissions in the reference bandwidth. It is positive when the interfering emissions would cause more degradation than thermal noise (see § 2.4 of this annex).

In certain cases, an administration may have reason to believe that, for its receiving earth station, a departure from the values associated with the earth station, as listed in Table 2, may be justified. Attention is drawn to the fact that for specific systems the bandwidths B or, for example in the case of demand assignment systems, the percentages of the time p and p_0 may have to be changed from the values given in Table 2.

2.1 Calculation of the noise temperature of the receiving system

The noise temperature, in degrees Kelvin, of the receiving system, referred to the output terminals of the receiving antenna, may be determined (unless specifically given in Table 1) from:

$$T_e = T_a + (l_{tl} - 1)290 + l_{tl} T_r \qquad (K) \tag{2}$$

where

- T_a: noise temperature contributed by the receiving antenna
- ℓ_{tl}: numerical loss in the transmission line (e.g. a waveguide) between the antenna terminal and the receiver front end
- T_r: noise temperature of the receiver front end, including all successive stages at the front end input.

For radio-relay receivers and where the waveguide loss of a receiving earth station is not known, a value of $\ell_{tl} = 1.0$ is used.

In case of determination of the coordination contours between two earth stations operating in the opposite direction of transmission, the following earth station receiving system noise temperatures should be used if the value is not provided in Table 3. This assumption is necessary because the receiving earth station takes the place of a receiving terrestrial station in the calculations.

Frequency range (GHz)	T_e (K)
$f < 10$	75
$10 < f < 17$	150
$f > 17$	300

2.2 Determination of the factor N_L

The factor N_L is the noise contribution to the link. In the case of a satellite transponder, it includes the up-link noise, intermodulation, etc. In the absence of table entries, it is assumed:

$$N_L = 1 \text{ dB for fixed-satellite links}$$

$$N_L = 0 \text{ dB for terrestrial links.}$$

2.3 Determination of the factor M_s

The factor M_s is the factor by which the link noise under clear-sky conditions would have to be raised to equal the permissible interference power.

2.4 Determination of the factor *W*

The factor *W* (dB) is the level of the radio-frequency thermal noise power relative to the received power of an interfering emission which, in the place of the former and contained in the same (reference) bandwidth, would produce the same interference (e.g., an increase in the voice or video channel noise power, or in the bit error ratio). The factor *W* generally depends on the characteristics of both the wanted and the interfering signals.

When the wanted signal is digital, *W* is usually equal to or less than 0 dB, regardless of the characteristics of the interfering signal.

3 Horizon antenna gain for a receiving earth station with respect to a transmitting earth station

For the determination of the coordination area of a transmitting earth station with respect to a receiving earth station in a bidirectionally allocated band, it is necessary to calculate the horizon antenna gain of the unknown earth station. In cases where the unknown receiving earth stations operate to geostationary satellites, Table 3 provides the necessary receiving earth station parameters for the calculation procedure, which is described in § 1.1 of Annex V.

In the case where the unknown receiving earth station operates to non-geostationary satellites, the horizon antenna gain to be used for all azimuths is provided in Table 3. The tabulated values were determined by using the method described in § 2.2 of the main body of the Appendix, which uses the maximum and minimum values of antenna horizon gain. For this purpose the maximum antenna horizon gain is the gain of the antenna for an off-axis angle equal to the minimum operating elevation angle. The minimum horizon gain is the gain at large off-axis angles, usually more than 36 or 48 degrees.

In determining the Non-GSO horizon gain entries in Table 3, the difference between the maximum and minimum horizon gain did not exceed 30 dB. Consequently, the Non-GSO horizon gain was taken as the lesser of the maximum horizon gain or 20 dB more than the minimum horizon gain. For the purpose of determining the Non-GSO horizon gain, the reference antenna pattern of § 3 of Annex III was used, except in cases noted in the Tables where a different pattern was deemed to be more appropriate.

NOTES to Table 1b:

(1) A: analogue modulation; N: digital modulation.

(2) The parameters for the terrestrial station associated with transhorizon systems have been used. Line-of-sight radio-relay parameters associated with the frequency band 5 725-7 075 MHz may also be used to determine a supplementary contour with the exception that G_x = 37 dBi.

(3) Feeder links of non-geostationary satellite systems in the mobile-satellite service.

(4) Feeder losses are not included.

(5) Actual frequency bands are 7 100-7 155 MHz and 7 190-7 235 MHz for space operation service and 7 145-7 235 MHz for the space research service.

NOTES to Table 2a:

(1) In these bands the terrestrial station parameters of line-of-sight radio-relay systems have been used. If an administration believes that, in the bands 2 160-2 200 MHz and 24 835-25 200 MHz, transhorizon systems need to be considered, the parameters associated with the frequency band 2 500-2 690 MHz may be used to determine the coordination area.

(2) A: analogue modulation; N: digital modulation.

(3) *E* is defined as the equivalent isotropically radiated power of the interfering terrestrial station in the reference bandwidth.

(4) This value is reduced from the nominal value of 50 dBW for the purposes of determination of coordination area, recognizing the low probability of high power emissions falling fully within the relatively narrow bandwidth of the earth station.

(5) The fixed service parameters provided in the column for 163-167 MHz and 272-273 MHz are only applicable to the band 163-167 MHz.

TABLE 2b

Permissible interference power	$P_r(p)$ (dBW) in B		–184		–142	–177	–216		–222	–154	–154		–176				

NOTES to Table 2b:

(1) In the band 1 670-1 700 MHz an additional contour for coordination with the meteorological aids service is required:

The coordination distance, *d* (km), for fixed earth stations in the meteorological-satellite service *vis-à-vis* stations in the meteorological aids service assumes a radiosonde altitude of 20 km and is determined as a function of the physical horizon elevation angle θ (degrees) for each azimuth, as follows:

$$d = 582 \left(\sqrt{1 + (0.254\,\theta)^2} - 0.254\,\theta \right) \qquad \text{for } \theta > 0$$

$$d = 582 \qquad \text{for } \theta > 0$$

The minimum and maximum coordination distances are (100 - f(GHz)/2) km and 582 km, and occur at physical horizon angles greater than 11° and less than 0°.

(2) A: analogue modulation; N: digital modulation.

(3) *E* is defined as the equivalent isotropically radiated power of the interfering terrestrial station in the reference bandwidth.

(4) In this band, the parameters for the terrestrial stations associated with transhorizon systems have been used. If an administration believes that transhorizon systems do not need to be considered, the line-of-sight radio-relay parameters associated with the frequency band 3.4-4.2 GHz may be used to determine the coordination area, with the exception that $E = 50$ dBW for analogue terrestrial stations; and $G_x = 37$ dBi. However, for the space research service only, noting footnote(5) when transhorizon systems are not considered, $E = 20$ dBW and $P_t = -17$ dBW for analogue terrestrial stations, $E = -23$ dBW and $P_t = -60$ dBW for digital terrestrial stations; and $G_x = 37$ dBi.

(5) These values are estimated for 1 Hz bandwidth and are 30 dB below the total power assumed for emission.

Permissible interference power	P_r (p) (dBW) in B					–151.2			–125	–125	–154 (11)	–142	–220	–216			–131	–131			

NOTES to Table 2c:

(1) A: analogue modulation; N: digital modulation.

(2) *E* is defined as the equivalent isotropically radiated power of the interfering terrestrial station in the reference bandwidth.

(3) In this band, the parameters for the terrestrial stations associated with transhorizon systems have been used. If an administration believes that transhorizon systems do not need to be considered, the line-of-sight radio-relay parameters associated with the frequency band 3.4-4.2 GHz may be used to determine the coordination area.

(4) Digital systems assumed to be non-transhorizon. Therefore G_x = 42.0 dBi. For digital transhorizon systems, parameters for analogue transhorizon systems above have been used.

(5) These values are estimated for 1 Hz bandwidth and are 30 dB below the total power assumed for emission.

(6) In certain systems in the fixed-satellite service it may be desirable to choose a greater reference bandwidth B. However, a greater bandwidth will result in smaller coordination distances and a later decision to reduce the reference bandwidth may require recoordination of the earth station.

(7) GSO satellite systems.

(8) Non-GSO meteorological satellites notified in accordance with Radio Regulations **S5.461A** may use the same coordination parameters.

(9) Non-GSO satellite systems.

(10) Space research earth stations in the band 8.4-8.5 GHz operate with non-GSO satellites.

(11) For large earth stations: Pr(p) = (G – 180) dBW

For small earth stations: Pr(20%) = 2 (G – 26) – 140 dBW for 26 < G ≤ 29 dBi

Pr(20%) = G – 163 dBW for G > 29 dBi

Pr(p)% = G – 163 dBW for G ≤ 26 dBi

(12) Applies to the broadcasting-satellite service in unplanned bands in Region 3.

NOTES to Table 3a:

(1) A: analogue modulation; N: digital modulation.

(2) Non-GSO.

(3) GSO.

(4) On-axis gain of the receive earth station antenna.

(5) Feeder links of non-geostationary satellite systems in the mobile-satellite service.

(6) Horizon antenna gain for the receive earth station (refer to § 3 of the main body of the Appendix).

(7) Minimum elevation angle of operation in degrees (non-GSO or GSO).

(8) Orbit of the space service in which the receiving earth station operates (non-GSO or GSO).

(9) The thermal noise temperature of the receiving system at the terminal of the receiving antenna (under clear-sky conditions). Refer to § 1.1 of this Annex for missing values.

(10) Horizon gain is calculated using the procedure of Annex III

(11) Non-GSO horizon gain, $G_e = G_{min} + 20$ dB (see § 2.2.1), with $G_{min} = 10 - 10 \log(D/\lambda)$, $D/\lambda = 13$ (refer to Annex III for definition of symbols)

(12) Unmanned space research is not a separate radiocommunication service and the system parameters are only to be used for the generation of supplementary contours.

NOTES to Table 3b:

(1) A: analogue modulation; N: digital modulation.

(2) On-axis gain of the receive earth station antenna.

(3) Feeder links of non-geostationary satellite systems in the mobile-satellite service.

(4) GSO satellite systems.

(5) Horizon antenna gain for the receive earth station (refer to § 3 of the main body of the Appendix).

(6) Minimum elevation angle of operation in degrees (non-GSO or GSO).

(7) Orbit of the space service in which the receiving earth station operates (GSO or non-GSO).

(8) The thermal noise temperature of the receiving system at the terminal of the receiving antenna (under clear-sky conditions). Refer to § 1.1 of this Annex for missing values.

(9) Horizon antenna gain is calculated using the procedure of Annex III.

(10) Horizon gain is calculated using the procedure of Annex III , except that the following antenna pattern may be used in place of that given in § 3 of that Annex: $G = 32 - 25 \log \phi$ for $1 \leq \phi < 48$; and $G = -10$ for $48 \leq \phi < 180$ (refer to Annex III for definition of symbols).

(11) Non-GSO horizon gain, $G_e = G_{max}$ (see § 2.2.1) for $G = 36 - 25 \log (\phi) > -6$ (refer to Annex III for definition of symbols).

(12) Non-GSO horizon gain, $G_e = G_{max}$ (see § 2.2.1) for $G = 32 - 25 \log (\phi) > -10$ (refer to Annex III for definition of symbols).

4 Predetermined coordination distances

The predetermined coordination distances specified in Tables 4 and 5 are used for transmitting and receiving earth stations, respectively, in cases defined by the corresponding frequency sharing situation.

TABLE 4

Frequency sharing situation		**Coordination distance (in sharing situations involving services allocated with equal rights) (km)**	***Source of information and comments*** *This column is for clarification purpose only and is not to be kept in the final text that may be included in Appendix **S7***
Earth station for which coordination area is determined	**Station in terrestrial service**		
Ground-based	Mobile (aircraft)	500	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix **S5**) for frequencies below 3 GHz No coordination distance is provided for frequencies above 3 GHz (e.g. in the band 5 725-7 075 MHz)*
Aircraft (mobile)	Ground-based	500	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix **S5**) for frequencies below 3 GHz Table S5-1 of Appendix **S5** (under the No. **S9.17**) for frequencies above 1 GHz*
Aircraft (mobile)	Mobile (aircraft)	1 000	
Ground-based in the bands: 400.15-401 MHz 1 675-1 700 MHz	Station in the meteorological aids service (radiosonde)	580	*Tables 1 and 2 (Section 3 of Annex 1 of Appendix **S5**)*
Aircraft (mobile) in the bands: 400.15-401 MHz 1 675-1 700 MHz	Station in the meteorological aids service (radiosonde)	1 080	
~~Ground based in the bands:~~ ~~454 – 456 MHz~~ ~~459 – 460 MHz~~	~~Ground based~~	~~500~~	*Table 1 (Section 3 of Annex 1 of Appendix **S5**)* *This case can be deleted since under **S5.286B** MSS earth stations shall not cause harmful interference to, or claim protection from, stations of the fixed or mobile services*

Ground-based in the radiodetermination-satellite service (RDSS) in the bands: 1 610-1 626.5 MHz 2 483.5-2 500 MHz 2 500-2 516.5 MHz	Ground-based	100	*Table S5-1 of Appendix **S5** (under the No. **S9.17**)*
Airborne earth station in the radiodetermination-satellite service (RDSS) in the bands: 1 610-1 626.5 MHz 2 483.5-2 500 MHz 2 500-2 516.5 MHz	Ground-based	400	
Receiving earth stations in the meteorological-satellite service	Station in the meteorological aids service	The coordination distance is considered to be the visibility distance as a function of the earth station horizon elevation angle for a radiosonde at an altitude of 20 km above mean sea level, assuming 4/3 Earth radius (see NOTE 1)	*Table S5-1 of Appendix **S5** (under the No. **S9.17**)* *Note 3 of Recommendation ITU-R IS.850*

NOTE 1 - The coordination distance, *d* (km), for fixed earth stations in the meteorological-satellite service vis-à-vis stations in the meteorological aids service assumes a radiosonde altitude of 20 km and is determined as a function of the physical horizon elevation angle θ (degrees) for each azimuth, as follows:

$$d = 100 \qquad \textit{for } \theta \geq 11$$

$$d = 582\left(\sqrt{1+(0.254\theta)^2} - 0.254\theta\right) \qquad \textit{for } 0 < \theta < 11,$$

$$d = 582 \qquad \textit{for } \theta \leq 0$$

The minimum and maximum coordination distances are 100 km and 582 km, and correspond with physical horizon angles greater than 11° and less than 0°.

TABLE 5

Non-GSO MSS feeder-link earth stations

Frequency sharing situation		Coordination distance (in sharing situations involving services allocated with equal rights) (km)	*Source of information and comments*
Earth station for which coordination area is determined	**Other service or station (station in terrestrial service or earth station)**		*This column is for clarification purpose only and is not to be kept in the final text that may be included in Appendix **S7***
Earth station operating in opposite direction in bands in which the FSS is already allocated	Ground-based stations in terrestrial services or Earth station operating in opposite direction of transmission	– 170 (in the band 19.3-19.7 GHz) – 300 (in the band 6 700-7 075 MHz)	*Table 3 (Section 3 of Annex 1 of Appendix **S5**)* *These distances would be in conflict with the ones calculated by using the method provided in the TG 1/6 DNR that may be used for revising Appendix **S7***
Transmit non-GSO MSS feeder-link earth station in the band 15.4-15.7 GHz	Aeronautical radionavigation	"the coordination distances required to protect the aeronautical radionavigation stations from harmful interference from feeder-link earth station emissions are: – 515 km from the aircraft landing surface for aircraft landing systems (ALS) – 600 km from aircraft using general purpose radars (MPR) – 270 km from the aircraft landing for radar sensing and measurement systems"	***S5.511C*** *Recommendation ITU-R S.1340 (recommends 7)* *If these distances have to be counted from the location of the earth station (as defined in **S1.173**) only the worst distance of 600 km is proposed to be retained in order to cover all cases of sharing (e.g. all systems used in aeronautical radionavigation stations). If these distances have to be counted from the terrestrial station, they are not "coordination distances" in the sense of the Radio Regulations and they might not be included in this table but only be referred in Article **S5** as another coordination method*

Receive non-GSO MSS feeder-link earth station in the band 15.4-15.7 GHz	Aeronautical radionavigation	"the threshold distance for the coordination of emissions from stations in the aeronautical radionavigation service with respect to feeder-link earth stations for the MSS based on an earth station antenna gain in the local horizontal plane of 11.5 dBi are: – 150 km from the ground segment for aircraft landing system (ALS) – 600 km from aircraft using general purpose radars – 60 km from the aircraft landing surface for radar sensing and measurement systems"	***S5.511A*** *Recommendation ITU-R S.1341 (recommends 5)* *If these distances have to be counted from the location of the earth station (as defined in* ***S1.173****) only the worst distance of 600 km is proposed to be retained in order to cover all cases of sharing (e.g. all systems used in aeronautical radionavigation stations). If these distances have to be counted from the terrestrial station, they are not "coordination distances" in the sense of the Radio Regulations and they might not be included in this table but only be referred in Article* ***S5*** *as another coordination method*
All bands and earth stations	Terrestrial mobile (aircraft)	500	*Table 3 (Section 3 of Annex 1 of Appendix* ***S5****)*

PLENARY MEETING

EUROPEAN COMMON PROPOSALS FOR THE WORK OF THE CONFERENCE

PART 7

Appendices S3 and S7, Resolutions 28 (WRC-95) and 95 (WRC-97), PP-98 resolutions

CONTENTS

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Portugal, Slovakia, Czech Rep., United Kingdom, Slovenia, Sweden, Switzerland, Ukraine

PART 7A

Agenda item 1.1 - Deletion of country names in footnotes to Article S5

1 Introduction

WRC-2000 agenda item 1.1 requests administrations to review the footnotes to the Table of Frequency Allocations with the view to delete their country footnotes or to have their country's name deleted from footnotes, if no longer required.

2 Background

In preparation of WARC-87 Europe developed several proposals in favour of new allocations for the mobile service.

At that point in time the aeronautical community through ICAO planned to have the instrument landing system (ILS) phased out by the end of this century and that the microwave landing system (MLS) would be the replacement system. Therefore WARC-87 added footnotes S5.181 (around 75 MHz used for ILS-marker beacons), S5.197 (around 108 MHz used for ILS-localizer and VOR) and S5.259 (around 330 MHz used for ILS-glide path transmitters) with an additional allocation for several European countries to the mobile service on a secondary basis and further restrictions to protect the ILS as long as required.

This decision was taken in order to indicate that the mobile service should use this spectrum after the aeronautical-radionavigation service would have ceased operation in these parts of the spectrum.

Meanwhile ICAO reviewed its concepts and extended the lifetime of the ILS far beyond the year 2000, the transition to MLS may not take place on a global basis and concluded, that the global navigation satellite system (GNSS Phase 2) is the most appropriate system which will meet all future requirements of the aeronautical radionavigation service.

3 Proposals

Considering the above described development and due to the fact that the three mentioned footnotes lost their duty, the concerned administrations which entered the footnotes collectively, propose the deletion of their names in footnotes S5.181, S5.197 and S5.259:

MOD EUR/13/255

S5.181 *Additional allocation:* in~~ Germany, Austria, Cyprus, Denmark,~~ Egypt~~, France, Greece,~~ Israel~~, Italy,~~ Japan, Jordan, Lebanon~~, Malta,~~ Morocco~~, Monaco, Norway,~~ and Syria~~, Sweden and Switzerland,~~ the band 74.8-75.2 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. In order to ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration which may be identified in the application of the procedure invoked under No. **S9.21**.

MOD EUR/13/256

S5.197 *Additional allocation:* in~~ Germany, Austria, Cyprus, Denmark,~~ Egypt~~, France, Italy,~~ Japan, Jordan, Lebanon~~, Malta,~~ Morocco~~, Monaco, Norway,~~ Pakistan, and Syria~~, and Sweden~~, the band 108-111.975 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. In order to ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration which may be identified in the application of the procedures invoked under No. **S9.21**.

MOD EUR/13/257

S5.259 *Additional allocation:* in ~~Germany, Austria, Cyprus, ~~the Republic of Korea~~, Denmark,~~ Egypt~~, Spain, France, Greece,~~ Israel~~, Italy,~~ Japan, Jordan~~, Malta,~~ Morocco~~, Monaco, Norway, the Netherlands,~~ and Syria~~ and Sweden~~, the band 328.6-335.4 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. In order to ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration which may be identified in the application of the procedure invoked under No. **S9.21**.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 7B

Agenda item 1.2 - Review of Appendix S3 with respect to spurious emissions for space services

Introduction

This agenda item covers finalizing the outstanding issues on spurious emissions limits for space services in the review of the generic spurious emission limits of Appendix S3 that was largely completed by WRC-97.

Appendix S3, as revised by WRC-97, contains two tables of maximum permitted spurious emission power levels. Table I contains levels currently in force, while Table II contains levels applicable to transmitters installed after 1 January 2003 and to all transmitters after 1 January 2012. Note 14 of Table II identifies the spurious emissions limits for space services as “design objectives” until after WRC-2000.

Following study and in accordance with Recommendation 66 (Rev.WRC-97), in particular *recommends* 1, 2 and 6, the CPM Report identifies several issues that require modification of Appendix S3:

i) Space services spurious emission limits.

The “design objective” qualification for space service limits (existing footnote 14 in Table II of Section II) should be suppressed and that, at this time, no changes to the attenuation values or the reference bandwidth for space services are appropriate.

ii) The limiting case of a very narrow-band or unmodulated signal in a wideband amplifier operating particularly in the space services.

A new self-explanatory paragraph 11*bis* should be added to Section II to cover this case.

iii) The special case of spurious emission limits applying in adjacent transponders within the same transmitting system.

A new self-explanatory paragraph 11*ter* should be added to Section II to cover this case.

The European proposal for paragraph 11*ter* is intended to cover the case of two transponders spaced far apart (see explanatory Note 1 below).

iv) Amateur earth stations operating below 30 MHz.

A new footnote 15 in Table II of Section II should applied to “Space services (earth stations)” to clear up any ambiguity for amateur earth stations.

To suppress the reference, in Table II of Section II, against “Amateur services operating below 30 MHz (including with SSB)”, to existing footnote 12 since it may add ambiguity; this particular service category includes all amateur stations.

v) Spurious emission limits for deep-space satellites.

Since there is no reason for spurious emission limits to be specified for *Deep Space* spacecraft, as defined by the ITU Radio Regulations, a new footnote 16 to Table II of Section II should be applied to “space services (space stations)” to indicate this exemption.

The CPM Report also identifies a further item requiring modifications to Appendix S3 which, although not directly related to agenda item 1.2, may be considered in order to bring attention to one particular WRC-97 decision that may be misunderstood. The modifications address:

vi) Radiodetermination (radar) spurious emission limits.

Section I of Appendix S3 adopted by WRC-97 includes paragraph 6 addressing measurement methods for radar systems. This may be taken to imply that the current spurious emission limits apply to radar systems. Radar systems were to have been exempted from the limits in Section I because the required measurement methods had not yet been determined. The measurement methods provided in Recommendation ITU-R M.1177 (referred to in paragraph 6) pertain to the spurious emission limits in Section II. Therefore, a new paragraph 6*bis* should be added to Section II to clarify any misunderstanding.

It is also preferable that spurious emission levels for radar systems should be based on radiated emissions, and not measured at the transmission line as called for in existing paragraph 1 of Appendix S3. This will ensure that the measured spurious emission levels account for the inherent selectivity of certain radar antennas that are integral to the transmitting system. To clarify this issue, existing paragraph 6 of Section I should be suppressed and a new footnote 17, applied to “Radiodetermination”, should be included in the Table II of Section II.

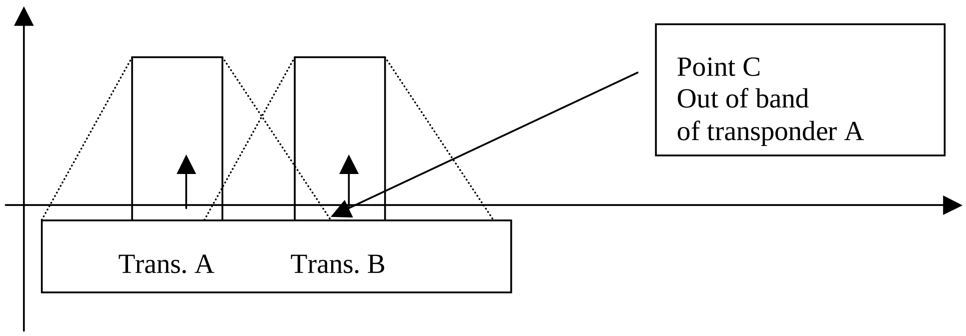
If the change indicated above is made, permitting the use of these measurement methods, the existing paragraph 8 of Section II should be modified to add the words “or appropriate” after the phrase “when it is not possible”.

Taking into account the conclusions of the CPM Report, Europe has developed proposals to revise Appendix S3 of the Radio Regulations at WRC-2000 to:

- include the relevant modifications highlighted in the six items discussed above;
- further split the space services categories of space stations and earth stations. This will allow different types of stations and their requirements to be clearly distinguished and also permit the application of different limits, if deemed appropriate at a later date. As a result of this split, a number of new categories are shown in Table II of Section II, however identical values for spurious emission levels to those currently indicated in Appendix S3 should be maintained. ITU-R Working Parties 4A, 8D and JWP 10-11S have indicated to TG 1/5 that such a split, based on definitions of RR Article S1, is appropriate.

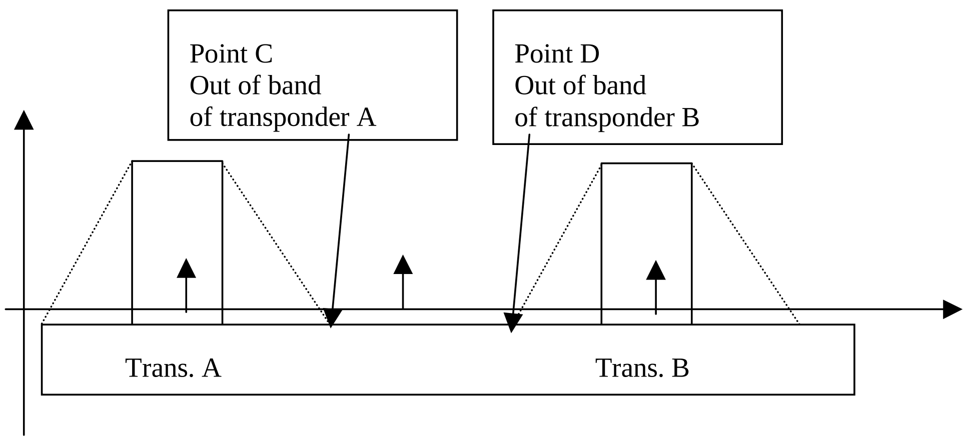
NOTE 1 - Explanation of the European proposal regarding adjacent satellite transponders.

Scheme with two closely spaced transponders



In this case the spurious emissions of the transponder A are covered by the out-of-band emissions of transponder B. The diagram shows that the CPM text is correct when you have two transponders near but if the two transponders are far, it is not the same situation.

Scheme with two transponders far apart



In this case the CPM text is not clear because the spurious emissions are not hidden by the out-of band emissions from the second transponder.

APPENDIX S3

Table of maximum permitted spurious emission power levels

(See Article **S3**)

NOC

1 to 5

Section I – Spurious emission limits for transmitters installed on or before 1 January 2003 (valid until 1 January 2012)

MOD EUR/13/258

6 ~~The measurement methods for radar systems should be guided by Recommendation ITU-R M.1177. For those radar systems for which acceptable methods of measurement do not exist, the lowest practicable power of spurious emission should be achieved.~~Radar systems are exempt from spurious emission limits under this section. The lowest practicable power of spurious emission should be achieved.

TABLE 1

Attenuation values and absolute mean power levels used to calculate maximum permitted spurious emission power levels for use with radio equipment

Section II – Spurious emission limits for transmitters installed after 1 January 2003 and for all transmitters after 1 January 2012

Application of these limits

NOC

7

MOD EUR/13/259

8 Guidance regarding the methods of measuring spurious emissions is given in the most recent version of Recommendation ITU-R SM.329. The e.i.r.p. method specified in that Recommendation should be used when it is not possible to measure the power supplied to the antenna transmission line, or for specific applications, such as radar, where the antenna is designed to provide significant attenuation at the spurious frequencies. Additionally, the e.i.r.p. method may need some modification for special cases, e.g. beam-forming radars.

NOC

9 to 11

ADD EUR/13/260

11*bis* As an emitted signal becomes more and more narrow (to the limiting case of an unmodulated carrier with theoretical necessary bandwidth of zero), the application of the term “necessary bandwidth” as used in determining the region where spurious emission limits apply to space services, becomes more and more difficult. In the limit, ±250% of necessary bandwidth (generally recognized as establishing the region beyond which spurious emissions are defined), approaches zero. Beacon and other unmodulated signals, such as those used in uplink and downlink circuits in control and tracking of satellites, are examples of a case where it is difficult to practically apply the term “necessary bandwidth” in determining where out-of-band emissions end, and spurious emissions begin. Pending further studies and definitive action by a future world radiocommunication conference, in calculating the region where spurious emission limits apply for transmitters using amplifiers to pass essentially an unmodulated signal (or a signal with very small bandwidth), the amplifier bandwidth is taken to be the necessary bandwidth (in calculating the regions where spurious emissions apply).

ADD EUR/13/261

11*ter* For satellites employing more than one transponder, and when considering the limits for spurious emission as indicated by Headnote 11 to Appendix **S3**, spurious emissions from one transponder may fall on a frequency at which a companion, second transponder is transmitting or in the guardband between two transponders. In these situations, if it can be shown that the level of spurious emission from the first transponder is below the fundamental emissions of the second transponder or below its out-of-band emissions, then the limits of Appendix **S3** should not apply to those spurious emissions.

MOD EUR/13/262

TABLE II

Attenuation values used to calculate maximum permitted spurious emission power levels for use with radio equipment

Service category in accordance with Article S1, or equipment type ~~15~~14	**Attenuation (dB) below the power supplied to the antenna transmission line**
All services except those services quoted below:	43 + 10 log (*P*), or 70 dBc, whichever is less stringent
~~Space services (earth stations) 10, 14~~	~~43 + 10 log (*P*), or 60 dBc, whichever is less stringent~~
Mobile earth stations [10, 15]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
Fixed earth stations [10, 15]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
~~Space services (space stations) 10, 14~~	~~43 + 10 log (*P*), or 60 dBc, whichever is less stringent~~
FSS space stations [10]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
MSS space stations [10]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
RNSS, ARNSS, RDSS and RLSS space stations [10]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
Space stations of the space research service [10, 16]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
Space stations (other than those in services mentioned above) [10]	43 + 10 log (*P*), or 60 dBc, whichever is less stringent
Radiodetermination [17]	43 + 10 log (*PEP*), or 60 dB, whichever is less stringent
Broadcast television [11]	46 + 10 log (*P*), or 60 dBc, whichever is less stringent, without exceeding the absolute mean power level of 1 mW for VHF stations or 12 mW for UHF stations. However, greater attenuation may be necessary on a case by case basis.
Broadcast FM	46 + 10 log (*P*), or 70 dBc, whichever is less stringent; the absolute mean power level of 1 mW should not be exceeded
Broadcasting at MF/HF	50 dBc; the absolute mean power level of 50 mW should not be exceeded
SSB from mobile stations [12]	43 dB below *PEP*
Amateur services operating below 30 MHz (including with SSB) ~~12~~15	43 + 10 log (*PEP*), or 50 dB, whichever is less stringent
Services operating below 30 MHz, except space, radiodetermination, broadcast, those using SSB from mobile stations, and amateur [12]	43 + 10 log (*X*), or 60 dBc, whichever is less stringent, where *X* = *PEP* for SSB modulation, and *X* = *P* for other modulation

(MOD) EUR/13/264

~~15~~14 In some cases of digital modulation (including digital broadcasting), broadband systems, pulsed modulation and narrow-band high-power transmitters for all categories of services, there may be difficulties in meeting limits close to ±250% of the necessary bandwidth.

ADD EUR/13/265

15 Amateur earth stations operating below 30 MHz are in the service category “Amateur services operating below 30 MHz (including with SSB)”.

ADD EUR/13/266

16 Space stations in the space research service intended for operation in deep space as defined by No. **S1.177**, are exempt from spurious emission limits.

ADD EUR/13/267

17 Radiodetermination (radar) system spurious emission dB attenuation shall be determined for radiated emission levels, not at the antenna transmission line. The measurement methods for determining the radiated spurious emission levels from the radar systems should be guided by Recommendation ITU-R M.1177.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 7C

Agenda item 1.3 - Review of Appendix S7

1 Introduction

In response to agenda item 1.3, a set of proposals is presented hereafter that fulfils the following objectives:

- replacement of the current text of Appendix S7 by the essential regulatory material within Recommendation ITU-R SM.[Doc. 1/1004], covering the frequency range 100 MHz - 105 GHz;
- relocation of the material relating to predetermined coordination distances from Appendix S5 to the revised Appendix S7;
- provisions for a procedure for updating the tables of system parameters within the revised Appendix S7 (Tables 1, 2 and 3);
- the completion of consequential changes elsewhere within the Radio Regulations.

2 Background

The revision of Appendix S7 was originally on the agenda of WRC-97. However, as the necessary technical studies could not be completed in time for that Conference, ITU-R Task Group 1/6 was set up to complete the work and to produce a draft new recommendation relating to methods for determining the coordination area around earth stations.

The ITU-R has now completed this work. The resulting recommendation exists as Recommendation ITU-R SM.[Doc. 1/1004]. This text is therefore available as a technical basis for a revision of Appendix S7 at WRC-2000. The ITU-R has indicated that the text can be used either as the basis of a revision of the Appendix S7 text or as a recommendation for incorporation by reference.

Chapter 7.2 of the CPM Report indicates the principal improvements that the material within the new recommendation will bring to Appendix S7. Section 7.2.3 of the Report offers five different methods for satisfying the agenda item:

- Method 1 proposes a complete replacement of the current text of Appendix S7 by the essential regulatory material from the new recommendation. However, the ITU-R agreed that there would be considerable advantage in being able to update the tables of system parameters between full revisions of Appendix S7, given that additional and modified allocations are made at each WRC, and given that systems and applications using the Article S5 frequency allocations nowadays change more often. Europe also agrees that this flexibility is desirable, and thus Method 1 is not supported.

- Method 5 proposes that the full recommendation be incorporated by reference. Europe believes that, whilst acknowledging the particular case of the parameter tables, the fundamental role of Appendix S7 determines that a stable and fully managed text should be located within the Radio Regulations, and not be incorporated by reference. Incorporation by reference could lead to almost constant change and this is neither necessary nor desirable in the case of Appendix S7. The experience of the ITU-R was that considerable attention had to be paid to the testing and validation of all changes in terms of their impact on coordination distances and the integrity of the procedures. This extensive effort could not be justified for frequent revisions.

  The CPM Report notes that there would be value in moving the information on predetermined coordination distances from Appendix S5 to Appendix S7 and that this cannot be achieved by incorporation by reference.

  Furthermore, the Special Committee concluded that there was only limited support for the approach using incorporation by reference. Method 5 is not therefore supported.

The three remaining methods (Methods 2-4) are based on the principal of a replacement text. Each offers a different method of achieving a procedure to allow the updating of the parameters in Tables 1, 2 and 3 of the revised Appendix S7.

- Method 4 suggests the replacement of the main text, but the incorporation by reference of Tables 1, 2 and 3 from the recommendation. This would result in a significant duplication of a large amount of material as the recommendation itself would need to be located in Volume 4 of the Radio Regulations under the provisions of Resolution 27. Method 4 is not therefore supported.
- Method 2 suggests the replacement of the main text with a permanent agenda item to allow the updating of the tables at each conference, based on allocation changes made at the previous conference. Europe believes that such a permanent agenda item might promote numerous small changes for consideration, where these may or may not be urgent. Method 2, whilst viable, is not therefore the preferred option. However, if it is anticipated that significant change to Tables 1, 2 or 3 would be needed at nearly every future conference, then the practical difference between Methods 2 and 3 becomes very small indeed, and the procedural overhead of Method 3 (see below) may no longer be justifiable.
- Method 3 calls for the establishment of a new WRC-2000 resolution that would provide a framework for a future conference to consider urgent changes to the tables of system parameters (Tables 1, 2 and 3 of ITU-R Recommendation ITU-R SM.[Doc. 1/1004]) when such a need arises.

The new resolution would create the mechanism that would permit the ITU-R to provide conclusions on the updating of the system parameters in a timely manner, so that a proposal can be made by the Director of the Radiocommunications Bureau to the Secretary General that Council place on the agenda of the next WRC an appropriate extraordinary agenda item to consider the ITU-R conclusions. Within the framework of this WRC Resolution a further resolution would need to be approved by the Radiocommunications Assembly to provide the practical implementation of this process.

On balance, of the five options proposed within the CPM Report, Method 3, as presented above, is the solution preferred by Europe. The proposals set out in section 3 below are structured on this basis. The method provides for stability and control of the main text, flexibility to update the tables, and offers a managed approach to the placing of changes to those tables before future conferences.

The ITU-R also proposed that the material relating to predetermined coordination distances, currently in Appendix S5, should be relocated within the revised Appendix S7, with appropriate references being inserted in Appendix S5 to indicate where the material is to be found. This proposal is supported within the Report of the Conference Preparatory Meeting. This advice is accepted and supported by Europe and the relevant proposals are set out in section 3 below.

3 Proposals

Modification to Appendix S7

MOD EUR/13/268

APPENDIX S7

Method<u>s</u> for the determination of the coordination area around an earth station in frequency bands between ~~1 GHz and 40 GHz shared between space and terrestrial radiocommunication services~~ <u>100 MHz and 105 GHz</u>

Reasons: The title is modified to reflect the changes introduced by the new Recommendation ITU-R SM.[Doc. 1/1004] where the frequency range has been extended to 100 MHz - 105 GHz and methods added for determining the coordination area of earth stations operating in bidirectionally allocated frequency bands.

MOD EUR/13/269

Replace the entire text of Appendix S7 by the text attached in Annex 1, that contains the essential regulatory text derived from Recommendation ITU-R SM.[Doc. 1/1004], together with the modified material from Appendix S5 relating to predetermined coordination distances, as included in Annex 1 of Chapter 7 of the CPM Report.

Reasons: The ITU-R has completed its studies and has developed a new Recommendation ITU-R SM.[Doc. 1/1004] on Methods for the determination of the coordination area around an earth station in frequency bands between 100 MHz and 105 GHz. This new recommendation is identified in the CPM text as the appropriate text to be used as the basis of a revision of Appendix S7.

Replacement of the existing text allows just the essential regulatory content of the new recommendation to be included, resulting in a considerably smaller text than would be the case if the whole recommendation were to be incorporated by reference into the Radio Regulations. It also permits the information on predetermined coordination distances to be moved into Appendix S7, allowing the benefits identified in the CPM Report, and the rationalization of the procedures on earth station coordination to be achieved. This approach also avoids inconsistencies between the existing regulatory provisions and the more generalized text within the recommendation.

Modification to Article S1

MOD EUR/13/270

S1.171 *coordination area:* When determining the need for coordination, t~~T~~he area ~~associated with~~surrounding an *earth station* ~~outside of which a *terrestrial station* sharing the same frequency band neither causes nor is subject to interfering *emissions* greater than a permissible level~~sharing the same frequency band with terrestrial stations, or surrounding a transmitting earth station sharing the same bidirectionally allocated frequency band with receiving earth stations, beyond which the permissible level of interference will not be exceeded.

NOC

S1.172

MOD EUR/13/271

S1.173 *coordination distance:* ~~Distance on a given azimuth from an *earth station* beyond which a *terrestrial station* sharing the same frequency band neither causes nor is subject to interfering *emissions* greater than a permissible level.~~When determining the need for coordination, the distance on a given azimuth from an *earth station* sharing the same frequency with terrestrial stations, or from a transmitting earth station sharing the same bidirectionally allocated frequency band with receiving earth stations, beyond which the permissible level of interference will not be exceeded.

Reasons: Consequential change identified by ITU-R.

Modifications to Article S9

MOD EUR/13/272

S9.17 *f)*[13] for any specific earth station or typical mobile earth station in frequency bands above ~~1 GHz~~100 MHz allocated with equal rights to space and terrestrial services, in respect of terrestrial stations, where the coordination area of the earth station includes the territory of another country, with the exception of the coordination under No. **S9.15**;

Reasons: The frequency range of Appendix S7 has been extended.

MOD EUR/13/273

S9.53 Thereafter, the requesting and responding administrations shall make every possible mutual effort to overcome the difficulties, in a manner acceptable to the parties concerned[1].

ADD EUR/13/274

---

1 **S9.53.1** In the process of coordination among earth stations and terrestrial stations, administrations are requested to use the methods for determining supplementary and auxiliary contours described in Recommendation ITU-R SM.[Doc. 1/1004], and, particularly for earth stations operating with non-GSO space stations, the TVG (Time Variant Gain) method described in the above recommendation and in Recommendations ITU-R SF.[XX] and ITU-R S.[XX].

Reasons: Article S9 subsection IIC refers to the “Action upon receiving a request for coordination”. Recognizing the requirements placed on administrations by the provision of S9.53 (“Thereafter, the requesting and responding administrations shall make every possible mutual effort

---

1 Footnote **S9.53.1** added to **S9.53**.

to overcome the difficulties, in a manner acceptable to the parties concerned.”), Recommendation ITU-R SM.[Doc. 1/1004] and Recommendations ITU-R SF.[XX] and ITU-R S.[XX] provide information to assist administrations in meeting the requirements of this regulatory provision.

Modifications to Annex 2A of Appendix S4

A.7 Earth station site characteristics

For a specific earth station:

a) The horizon elevation angle in degrees and, in the case of a station submitted in accordance with Appendix **S30A**, the antenna gain in the direction of the horizon for each azimuth around the earth station.

ADD EUR/13/275

b) The distance in kilometres from the earth station to the horizon for each azimuth around the earth station.

SUP EUR/13/276

b)

SUP EUR/13/277

c)

ADD EUR/13/278

c) That is operating to an associated geostationary space station and having due regard to possible inclined-orbit operation of the associated space station:

i) the planned minimum angle of elevation of the antenna in the direction of maximum radiation in degrees from the horizontal plane;

ii) the planned range of operating azimuthal angles for the direction of maximum radiation in degrees, clockwise from True North.

ADD EUR/13/279

d) That is operating to associated non-geostationary space stations, the minimum angle of elevation of the antenna in the direction of maximum radiation in degrees from the horizontal plane for each azimuth around the earth station.

(MOD) EUR/13/280

~~d~~e) The altitude (metres) of the antenna above mean sea level.

Reasons: Additional provisions are needed in Appendix S4 to cover all data elements required to determine the coordination area of a particular earth station using the revised Appendix S7.

Modifications to Table S5-1 and section 3 of Annex 1 to Appendix S5

(NOTE - Only entries relating to earth station coordination are shown.)

TABLE S5-1

Technical conditions for coordination
(see Article **S9**)

MOD EUR/13/281

Reference of Article S9	Case	Frequency bands (and Region) of the service for which coordination is sought	Threshold/condition	Calculation method	Remarks
No. **S9.15** Non-GSO/ terrestrial	A specific earth station or a typical earth station in respect of terrestrial stations in frequency bands for which a footnote refers to No. **S9.11A** allocated with equal rights to space and terrestrial services, where the coordination area of the earth station includes the territory of another country	See Table S5-2	The coordination area of the earth station covers the territory of another administration	~~See § 2 of Annex 1 of this Appendix~~Appendix **S7**	

Reasons: There is no calculation method in § 2 of Annex 1. The applicable calculation method is Appendix S7 as § 3 of Annex 1 can be deleted following the revision of Appendix S7. Also see proposal EUR/13/287.

MOD EUR/13/282

No. **S9.16** Terrestrial/ non-GSO	A transmitting station in a terrestrial service within the coordination area of an earth station in a non-GSO network in frequency bands for which a footnote refers to No. **S9.11A**	See Table S5-2	Transmitting terrestrial station is situated within the coordination area of a receiving earth station	~~See § 2 of Annex 1 of this Appendix~~	The coordination area of the affected earth station has already been determined using the calculation method of ~~No. **S9.15**~~Appendix **S7**

Reasons: There is no calculation method in § 2 of Annex 1. The reference to a calculation method is not appropriate since, as mentioned in the right hand column, the method of Appendix S7 has already been used under S9.15. Also see proposal EUR/13/287.

MOD EUR/13/283

No. **S9.17** GSO, non-GSO/ terrestrial	A specific earth station or a typical mobile earth station in frequency bands above ~~1 GHz~~100 MHz allocated with equal rights to space and terrestrial services in respect of terrestrial stations, where the coordination area of the earth station includes the territory of another country, with the exception of the coordination under No. **S9.15**	Any frequency band allocated to a space service, except those mentioned in the Plans in Appendix **S30A**	The coordination area of the earth station covers the territory of another administration	Appendix **S7** ~~(for earth stations in the radiodetermination-satellite service (RDSS) in the bands: 1 610-1 626.5 MHz, 2 483.5-2 500 MHz and 2 500-2 516.5 MHz, see Remarks column)~~ ~~1)The coordination area of aircraft earth stations is determined by increasing the service area by 1 000 km with respect to the aeronautical mobile service (terrestrial) or 500 km with respect to terrestrial services other than the aeronautical mobile service~~	~~NOTE – For RDSS earth stations, a uniform coordination distance of 400 km corresponding to an airborne earth station shall be used. In cases where the earth stations are all ground-based, a coordination distance of 100 km shall be used~~	

Reasons: The frequency range has been extended down to 100 MHz following the revision of Appendix S7. The predetermined coordination distances will now be in Appendix S7 and hence do not need to be included here.

MOD EUR/13/284

No. **S9.17** GSO, non-GSO/ terrestrial (*cont.*)				2)~~For receiving earth stations in the meteo-rological-satellite service in frequency bands shared with the meteorological aids service, the coordina-tion distance is consi-dered to be the visibility distance as a function of the earth station horizon elevation angle for a radiosonde at an altitude of 20 km above mean sea level, assuming 4/3 Earth radius~~	Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending the decision of WRC-99 on the revision of these two Appendices	

Reasons: The predetermined coordination distances will now be in Appendix S7 and hence do not need to be included here.

MOD EUR/13/285

No. **S9.17A** GSO, non-GSO/ GSO, non-GSO	A specific earth station in respect of other earth stations operating in the opposite direction of transmission in frequency bands allocated with equal rights to space radiocommunication services in both directions of transmission, where the coordination area of the earth station includes the territory of another country or the earth station is located within the coordination area of a coordinated earth station, with the exception of the frequency bands subject to the Plans in Appendix **S30A**	Any frequency band allocated to a space service	The coordination area of the earth station covers the territory of another administration or the earth station is located within the coordination area of an earth station	~~i) For bands in Table S5-2, see § 2 of Annex 1 of this Appendix~~ ~~ii) See Recommendations ITU-R IS.847, ITU-R IS.848 and ITU-R IS.849~~ Appendix **S7**		

Reasons: Consequential change owing to revision of Appendix S7 to cover earth stations within both GSO and non-GSO systems.

NOC EUR/13/286

No. **S9.21** Terrestrial, GSO, non-GSO/ terrestrial, GSO, non-GSO	A station of a service for which the requirement to obtain the agreement of other administrations is included in a footnote to the Table of Frequency Allocations, referring to No. **S9.21**	Band(s) indicated in the relevant footnote	Condition: Incompatibility established by the use of Appendices **S7**, **S8**, technical annexes of Appendices **S30**, **S30A** and **S30B**, pdf values specified in some of the footnotes, other technical provisions of the Radio Regulations or ITU-R Recommendations as appropriate	Methods specified in, or adapted from, Appendices **S7**, **S8**, **S30**, **S30A**, **S30B**, other technical provisions of the Radio Regulations or ITU-R Recommendations	

Modification of Table S5-1A of Appendix S5

MOD EUR/13/287

TABLE S5-~~1A~~2

Reasons: Editorial error made by WRC-95, not corrected at WRC-97.

Modification of the table text of Table S5-1A of Appendix S5

MOD EUR/13/288

Applicability of No. S9.11A for space services

NOTE - Annex 1 contains the relevant coordination thresholds for sharing between the mobile-satellite service (MSS) (space-to-Earth) and terrestrial services~~ as well as the relevant coordination areas for mobile earth stations operating below 3 GHz~~. It also contains the relevant coordination thresholds for sharing between non-GSO MSS feeder links (space-to-Earth) and terrestrial services~~ as well as the relevant coordination areas for earth stations providing feeder links for non-GSO satellites operating in the MSS and for non-GSO FSS earth stations~~.

Reasons: Consequential to the inclusion of the predetermined coordination distances in Appendix S7.

Modification of Table S5-2 of Annex 1 to Appendix S5

MOD EUR/13/289

TABLE AS5-2

Reasons: This table needs to be renumbered in order to avoid the current confusion with the references to Table S5-2 contained in Table S5-1. The real Table S5-2 is the current Table S5-1A (see EUR/13/287).

Suppression of section 2 of Annex 1 to Appendix S5

SUP EUR/13/290

2 Hard limits

Reasons: This section contains hard limits, hence not coordination thresholds. These limits should therefore not appear in Appendix S5. They already appear in Article S21, which is the proper place for such limits. They can therefore be suppressed from Appendix S5 without any consequence.

Suppression of section 3 of Annex 1 to Appendix S5

SUP EUR/13/291

3 Coordination areas for mobile earth stations operating below 3 GHz and earth stations providing feeder links for non-GSO satellites operating in the MSS and for non-GSO FSS earth stations

Reasons: The relevant material with appropriate modifications will now be available in Appendix S7. Relocating the material in a central location in Appendix S7 avoids the present duplication of text in Appendix S5.

Suppression of Resolution 60

SUP EUR/13/292

RESOLUTION 60

Relating to information on the propagation of radio waves used in the determination of the coordination area

Reasons:

1 Resolution 60 provided a mechanism for the updating of the propagation material in Appendix S7 independently from full updates of the Appendix S7 text. Recommendation ITU-R SM.[Doc. 1/1004] contains new calculation methodologies that have a greater degree of integration with the propagation models, and it is now less straightforward to adopt new propagation material without checking for consequential changes that might be necessary elsewhere in the text.

2 New arrangement will need to be made for the ongoing maintenance of Recommendation ITU-R SM.[Doc. 1/1004]. The relevant lead group might prefer to request changes to the propagation material and/or be notified of improvements made by SG 3 via the now effective liaison statement process.

MOD EUR/13/293

ANNEX 4 TO RESOLUTION 27 (Rev.WRC-97)

List of ITU-R Recommendations referred to in the Radio Regulations[1]

Recommendation	Title	Status[2]	Document	RR provision[3]
~~ITU-R SF.356-4~~	~~Maximum allowable values of interference from line-of-sight radio-relay systems in a telephone channel of a system in the fixed-satellite service employing frequency modulation, when the same frequency bands are shared by both systems~~	~~NOC~~	~~1997 SF Series~~	~~AP S7, § 2.3.1, Note 2~~
~~ITU-R SF.357-4~~	~~Maximum allowable values of interference in a telephone channel of an analogue angle-modulated radio-relay system sharing the same frequency bands as systems in the fixed-satellite service~~	~~MOD~~	~~1997 SF Series~~	~~AP S7, § 2.3.1, Note 2~~
~~**ITU-R IS.847-1**~~	~~Determination of the coordination area of an earth station operating with a geostationary space station and using the same frequency band as a system in a terrestrial service~~	~~NOC~~	~~1997 IS Series~~	~~**AP S5**, **Table S5-1**~~ ~~**AP S5**, **Annex 2**,~~ ~~**Tables 2** and **3**~~
~~**ITU-R IS.848-1**~~	~~Determination of the coordination area of a transmitting earth station using the same frequency band as receiving earth stations in bidirectionally allocated frequency bands~~	~~NOC~~	~~1997 IS Series~~	~~**AP S5**, **Table S5-1**~~
~~**ITU-R IS.849-1**~~	~~Determination of the coordination area for earth stations operating with non-geostationary spacecraft in bands shared with terrestrial services~~	~~NOC~~	~~1997 IS Series~~	~~**AP S5**, **Table S5-1**~~ ~~**AP S5**, **Annex 2**,~~ ~~**Tables 2** and **3**~~
~~**ITU-R M.1185-1**~~	~~Method for determining coordination distance between ground based mobile earth stations and terrestrial stations operating in the 148.0-149.9 MHz band~~	~~MOD~~	~~1997 M Series, Part 5~~	~~**AP S5**, **Annex 1**, **§ 3.2**, **Table 1**~~ ~~Resolution 46 (Rev.WRC-97), Annex 2, Table 1~~

Reasons: The proposed revision of Appendix S7 is based upon the essential regulatory text of Recommendation ITU-R SM.[Doc. 1/1004]. This new recommendation has drawn upon, and in some cases updated, the material of the recommendations identified for suppression in Annex 4 of Resolution 27. As the material in these recommendations is either obsolete or represents duplication, they should no longer be incorporated by reference within the Radio Regulations and the reference to them can be suppressed.

NOTE **-** It is assumed that this action and the modifications to Appendix S5 will also result in the deletion of these recommendations from Volume 4 of the Radio Regulations.

Suppression of Recommendation 105 (WRC-95)

SUP EUR/13/294

RECOMMENDATION 105 (WRC-95)

Further work by ITU-R on determination of the coordination area around earth stations operating with geostationary-satellite networks in the fixed-satellite service and earth stations providing feeder links to non-geostationary-satellite networks in the mobile-satellite service operating in opposite directions of transmission

Reasons: Consequential change. While the procedures called for in this recommendation have been provided by Recommendation ITU-R SM.[Doc. 1/1004], it is recognized that not all the technical coordination parameters have yet been identified. However, new Resolution [AAA] will provide the mechanism by which these parameters can be updated, and hence Recommendation 105 should be suppressed.

Suppression of Recommendation 711

SUP EUR/13/295

RECOMMENDATION 711

Relating to the coordination of earth stations

Reasons: Consequential change. While the procedures called for in this recommendation have been provided by Recommendation ITU-R SM.[Doc. 1/1004], it is recognized that not all the technical coordination parameters have yet been identified. However, new Resolution [AAA] will provide the mechanism by which these parameters can be updated, and hence Recommendation 711 should be suppressed.

Modification to Resolution 712

MOD EUR/13/296

RESOLUTION 712 (Rev.WRC-~~95~~2000)

Consideration by a future competent World Radiocommunication Conference of issues dealing with allocations to space services

The World Radiocommunication Conference (~~Geneva, 1995~~Istanbul, 2000),

considering

a) that the agenda of WARC-92 called for the development of new Recommendations and Resolutions relating to allocations to space services which were not placed on the agenda of that Conference;

b) that Recommendation ITU-R SA.363-5 recommends that frequencies below 1 GHz are technically suitable for telecommand of satellites operating below an altitude of 2 000 km;

c) that the United Nations Conference on Environment and Development (UNCED) (Rio de Janeiro, 1992) identified an urgent need for systematic observations of forest cover, and that such observations can best be performed using frequencies in the range 420-470 MHz;

d) that Resolution 35 of the Plenipotentiary Conference (Kyoto, 1994) considered that application of the latest telecommunication and information technologies, especially those associated with space systems, can be extremely useful in implementing and conducting environment protection activities such as monitoring air, river, harbour and sea pollution, remote sensing, wildlife studies, forestry development, and others;

e) that the status of existing allocations available for use by active space-based sensors between 1 and 25 GHz, in frequency bands shared with radiolocation or radionavigation systems, needs to be reviewed in order to facilitate worldwide usage by active space-based sensors;

f) that the allocations to the Earth exploration-satellite service in the frequency bands 8.025-8.4 GHz and 18.6-18.8 GHz are complex and not uniform worldwide, and that the band 18.6-18.8 GHz is vital for passive sensing of ecologically important data;

g) that the allocation of the frequency band 13.75-14 GHz to the fixed-satellite service by WARC-92 reduced the total bandwidth available for active space-based sensors in the frequency range 13-14 GHz, which is important for wideband sensor instruments, e.g. radar altimeters, scatterometers;

h) that future active Earth sensing requirements for monitoring environmental data in the 35 GHz and 95 GHz ranges have been identified;

i) that ITU-R has agreed to certain important technical parameters required for coordination of the space services under Appendix **S7**,

resolves

that, based on proposals from administrations and taking into account the results of studies in the Radiocommunication Study Groups and the 1997 Conference Preparatory Meeting (CPM-97), WRC-97 should consider the following matters:

1 provision of up to 3 MHz of frequency spectrum for the implementation of telecommand links in the space research and space operation services in the frequency range between 100 MHz and 1 GHz;

2 provision of up to 3.5 MHz of frequency spectrum to the Earth exploration-satellite service (active sensors) in the frequency range 420-470 MHz;

3 use of existing allocations by space-based active sensors operating in the Earth exploration-satellite and space research services in frequency bands shared with the radiolocation or radionavigation services, between 1 GHz and 25 GHz, with a view to the possibility of establishing common worldwide primary allocations;

4 use of existing allocations in the frequency range from 7 GHz to 20 GHz to the Earth exploration-satellite, meteorological-satellite, space research and space operation services, with a view to the possibility of establishing common worldwide primary allocations to these services in appropriate bands, taking into account Recommendation **706**;

5 provision of up to 500 MHz of frequency spectrum around 35 GHz and up to 1 GHz of frequency spectrum around 95 GHz for use by space-based active Earth sensors;

6 inclusion of ITU-R approved technical coordination parameters in Appendix **S7**, ~~taking into account Resolution **60** and Recommendation **711**,~~taking into account Resolution [EUR/13/9],

invites the Radiocommunication Study Groups

to carry out the necessary studies, taking into account the present uses of allocated bands, with a view to presenting, at the appropriate time, the technical information likely to be required as a basis for the work of the Conference,

instructs the Secretary-General

to bring this Resolution to the attention of the international and regional organizations concerned.

Reasons: Proposals EUR/13/292 and EUR/13/295 call for the suppression of Resolution 60 and Recommendation 711. Resolution 60 is recommended for suppression following the ITU-R work in revising Appendix S7 (EUR/13/269). Recommendation 711 can also be suppressed if Resolution [EUR/13/9] is approved.

Draft Resolution EUR/13/9

ADD EUR/13/297

RESOLUTION [EUR/13/9] (WRC-2000)

Consideration by a future competent World Radiocommunication Conference of revisions to technical coordination parameter tables contained in Annex VII of Appendix S7

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that Appendix **S7** to the Radio Regulations provides a method for the determination of the coordination area which requires assumed technical coordination parameters for the unknown terrestrial station or earth station;

b) that these technical coordination parameters are contained in Tables 1, 2 and 3 of Annex VII of Appendix **S7** (WRC-2000);

c) that the technical coordination parameter tables contained in Appendix **S7** are based directly on texts of the ITU-R;

d) that ITU-R studies on radiocommunication systems are continuing, and therefore the conclusions of these studies are subject to change and may in future show the need to revise those sections of Appendix **S7** which incorporate the technical coordination parameter tables;

e) that the technical coordination parameter tables may require to be updated when new frequency allocations are made at WRCs;

f) that the technical coordination parameter tables do not show numerical values for all the necessary parameters of certain space radiocommunication services and terrestrial radiocommunications services sharing frequency bands with equal rights,

recognizing

a) that Recommendation ITU-R SM.[Doc. 1/1004] was developed by the ITU-R as a basis for revision to Appendix **S7**;

b) that there is a need for future conferences to consider the revision of the tables of technical coordination parameters on an irregular basis,

invites

the ITU-R to continue to study technical parameters concerned with the determination of the coordination area, and to maintain the relevant ITU-R texts in a format which would permit direct insertion into Appendix **S7** in place of the existing Annex VII,

resolves

that when the ITU-R has come to the conclusion that a revision of Annex VII of Appendix **S7** is warranted, based on the latest available information on technical coordination parameter values, the Director of the Radiocommunication Bureau shall so inform the Secretary-General of ITU and send him the proposed amendments to Appendix **S7**, given in Annex 2 of the most recent version of Recommendation ITU-R SM.[Doc. 1/1004],

requests

that the Council then place, as an extraordinary item, on the agenda of the next world radiocommunication conference, the consideration of the conclusion of the ITU-R.

Reasons: This proposed Resolution provides the framework for updating the technical coordination parameter tables in support of Method 3 for fulfilling the agenda item as set out in Chapter 7.2.3 of the CPM Report.

Resolution 712 and Recommendations 105 and 711 require the updating of the technical coordination parameter in Appendix S7. This Resolution provides the mechanism by which this requirement can be achieved. In addition, the work performed by the ITU-R in revising Appendix S7 and the approval of this Resolution will permit Resolution 60 and Recommendations 105 and 711 to be suppressed (see proposals EUR/13/292, EUR/13/294 and EUR/13/295).

ANNEX 1 TO PART 7C OF THE EUROPEAN COMMON PROPOSALS

APPENDIX S7

(Will be provided as Addendum 1 to Addendum 7 of Document CMR2000/13)

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey

PART 7D

Agenda item 7.1 - Report of the Director, BR - Rules of Procedure

ARTICLE S13

Instructions to the Bureau

Introduction

The present structure of Article S13 dealing with the Rules of Procedure of the Radio Regulations Board has resulted in some misunderstanding as to what was intended by the WRC-97. The RRB have, on a provisional basis, developed some rules to clarify the application of these provisions. The purpose of these proposals is to modify Article S13 to clarify the sequence of these various provisions. In these proposals there is no major change in substance (except as mentioned in the following paragraph), mainly a rearrangement of the provisions.

In addition, there are situations when administrations may wish to react to decisions of the RRB and submit documents to the next meeting. Under the present situation and in accordance with the current No. S13.18, the minutes of the RRB meetings are not available until after the subsequent Board meeting starts - about three months later. It should be possible for the RRB to approve and make its minutes available before the start of the subsequent meeting, therefore a modification to No. S13.18 is proposed.

Section III – Maintenance of the Rules of Procedure by the Bureau

(MOD) EUR/13/298

S13.13 The Rules of Procedure shall include, inter alia, calculation methods and other data required for the application of these Regulations. These shall be based upon the decisions of world radiocommunication conferences and the Recommendations of the Radiocommunication Sector. Where requirements arise for new data for which there are no such decisions or Recommendations the Bureau shall develop such data in accordance with No. ~~**S13.14**~~**S13.15**, and shall revise them when appropriate decisions or Recommendations are available.

MOD EUR/13/299

S13.14 ~~The Bureau shall submit to the Board the final drafts of all proposed changes to the Rules of Procedure. The Rules of Procedure approved by the Board shall be published and shall be open for comment by administrations. In case of continuing disagreement, the matter shall be submitted by the Director in his report, with the agreement of the concerned administration, to the next world radiocommunication conference. The Director of the Bureau shall also inform the appropriate study groups of this matter. Pending resolution of the matter, the Board and the Bureau shall continue to use the particular Rule of Procedure in dispute but, following resolution of the matter by a decision of a world radiocommunication conference, the Board shall promptly review and revise as necessary the Rules of Procedure and the Bureau shall review all relevant findings.~~ Any administration may request a review or a study of the Rules of Procedure or may submit proposals for either changes to the existing Rules of Procedure or for new Rules of Procedure. Any such proposals for changes to existing Rules or new Rules shall be submitted to the Bureau as soon as possible so that the Bureau may make these proposals available to other administrations for comment before submitting the proposal to the Board.

ADD EUR/13/300

S13.14A The Board may also request the Bureau to undertake studies with respect to the Rules of Procedure and such reviews shall be treated in accordance with **S13.15**.

MOD EUR/13/301

S13.15 ~~If an administration, or the Board or the Bureau identifies a need for a special study, in relation to the Rules of Procedure, of any provisions of these Regulations or of a regional agreement with an associated frequency allotment or assignment plan, the case shall be handled under No. **S13.14**.~~The Bureau shall, where appropriate, prepare draft modifications or additions to the Rules of Procedure which shall be made available for comment before being submitted to the Board. The Director of the Bureau shall submit to the Board the final drafts of all proposed changes to the Rules of Procedure. The same shall apply if as a consequence of the review of a finding or other action by the Board it is necessary to re-examine the Rules of Procedure.

MOD EUR/13/302

S13.16 The Rules of Procedure shall be maintained and published in a form that will facilitate easy modification and maximize their value to administrations and other users. The Rules of Procedure approved by the Board shall be published and shall be open for comment by administrations. In case of continuing disagreement, the matter shall be submitted by the Director in his report, with the agreement of the concerned administration, to the next world radiocommunication conference. The Director of the Bureau shall also, where appropriate, inform the relevant study groups of this matter. Pending resolution of the matter, the Board and the Bureau shall continue to use the particular Rule of Procedure in dispute but, following resolution of the matter by a decision of a world radiocommunication conference, the Board shall promptly review and revise as necessary the Rules of Procedure and the Bureau shall review all relevant findings.

Section IV – Board documents

MOD EUR/13/303

S13.17 ~~The Bureau shall, where appropriate, prepare draft modifications or additions to the Rules of Procedure which shall be made available for comment before being submitted to the Board.~~ One week beforehand, the draft agenda of each Board meeting shall be sent by facsimile, or mailed, to all administrations and shall also be made available in electronic form. At the same time, all documents which are both referred to in that draft agenda and available at that time shall be sent by facsimile, or mailed, to those administrations requesting them as well as simultaneously being made accessible in electronic form.

MOD EUR/13/304

S13.18 Within one week after a meeting of the Board, a summary of all decisions taken in that meeting~~, as well as the~~. No later than six weeks after each Board meeting the approved minutes of ~~the preceding~~that meeting, shall be~~ published. These shall be~~ circulated to administrations by means of a circular-letter from the Bureau and~~ then~~ made available in electronic form.

MOD EUR/13/305

S13.19 A copy of all documents considered at the Board's meetings, including the minutes, shall be available for public inspection by administrations in the offices of the Bureau and shall be available in electronic form as soon as possible.

PART 7E

PP-98 resolutions

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey

PART 7E1

PP-98 RESOLUTION 86

Date of bringing into use of satellite network frequencies

1 Introduction

During the past year there has been a situation in which the bringing into use of frequencies to a satellite network has resulted in some problems. This arose as a result of a satellite being tested for a few days at one orbital position and then moved to another orbital position. The testing at the first position was then used to indicate compliance with the date limits of the RR for the bringing into use of frequencies and thus avoid the consequential loss of protection for frequencies and the network concerned. While the term “date of bringing into use” is not defined in the RR, the closest phrase that exists in the RR is in No. S13.6 which relates to a review by the BR and this provision uses the term “regular operation in accordance with the notified required characteristics” is used. The term “regular use” is also used in No. S9.49 which deal with the bringing back into use after a period of suspension. Moreover, in at least one administration, the testing for a short period of time does not comply with the national requirements to bring the frequencies into service by a certain date limit.

One question that has been raised is whether there should be some flexibility in the application of this type of provision. However, it is to be noted that the Radio Regulations (1998 version) clearly indicate that the procedures for the API, coordination and notification of satellite networks should not start before five years in advance of the planned "in-service date" (No. S9.1). In addition, these Regulations provide for the extension of this “in-service date” by up to two years under certain circumstances such as launch problems and satellite design problems (Nos. S11.44C to S11.44I). The Radio Regulations seem to provide sufficient flexibility to deal with problems that may arise in the implementation of satellite networks so that a planned satellite can be brought into use within either the original five year period or the seven year extended period as provided for in the RR. If too much flexibility were provided in the Regulations, then the intent of these changes would be lost.

The discussion of this issues at the CPM and the conclusions of the CPM in section 7.5.2.1 have been taken into consideration.

2 Proposals

It is proposed to modify Appendix S4 Annex 2A, item A.2 (the explanation of the date of bringing into use) as follows as well as similar changes to Annexes of Appendices S30, S30A and S30B:

MOD EUR/13/306

a) The date (actual or foreseen, as appropriate) of bringing the frequency assignment (new or modified) into use. The date of bringing into use denotes the date at which the frequency is brought into regular operation to provide the published Radiocommunication service with the technical parameters within the technical characteristics notified to the Bureau. Whenever the assignment is changed in any of its basic characteristics (except in the case of a change in § A.1 *a)*, the date to be given shall be that of the latest change (actual or foreseen, as appropriate).

1) Pending further studies by ITU-R on the applicability of the term "regular operation" to non-GSO networks, the condition of regular operation shall be limited to GSO networks.

EUR/13/307

Similar changes to Annex 2 of Appendix S30 (item 4), Annex 2 of Appendix S30A (item 1.4) and Annex 2 of Appendix S30B (item 1.4).

Proposals submitted by the following administrations

Germany, Austria, Belgium, Croatia, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey

PART 7E2

PP-98 RESOLUTION 86

Satellite coordination procedures

1 Background

The PP-98 adopted Resolution 86 on the coordination and notification procedures for satellite networks. The objective of this Resolution is to permit WRC-2000 and subsequent WRCs to review and update the various coordination and notification procedures for satellite networks to achieve additional simplification of the procedures and cost savings for the BR and for administrations. During the past few years, the complexity of satellite networks has increased with the resulting increase in the complexity in the ITU notifications. This increased complexity together with the increased volume of notices to the ITU has resulted in very large backlogs in the processing of notices. Another important aspect is that the operational use of many satellite networks changes over time and it is probably not practical to expect operators and administrations to keep the ITU database current. One of the other purposes of Resolution 86 is to correct any problems that arise in the application of the procedures.

Another important change during the past few years has been the increasing role of satellite operators. An example of this is the coordination arrangements that have been made in the MSS in the L band, in which there are general intergovernmental agreements and then the operators meet on an annual basis to modify the operational requirements for the following year. This particular process may not work for other bands/services, but it does reflect the need to use new approaches to coordination.

The increasing complexity and volume of notices has increased the complexity and amount of work for BR and administrations, and thus the backlogs. It is not realistic to expect that BR will be provided with the necessary resources to be able to process the notices within the time period specified in the RR based on the present procedures. On the other hand, the time to build and launch satellites is decreasing significantly and the long processing delays by BR, are not consistent with these shorter times. As an example, the delay for the processing of a coordination request by BR is longer than some of the contracted satellite construction and launch times. Consequently, the most logical approach would seem to be to try to find some considerable simplification to the ITU procedures without sacrificing the major objective of the procedures. The present proposals address some of the issues related to the backlog, but further improvements would be necessary to have a significant impact on the backlogs.

2 Coordination procedures

There are a number of related changes to the coordination procedures that would result in considerable simplicity and cost savings for both BR and administrations.

2.1 Separation of uplink and downlink data

At the present time, the data requirements are complicated by the need to provide strapping tables to cover all of the possible combinations of the up and downlink frequencies, however, in the end it is necessary to identify separate coordination requirements for the two directions of transmissions. With the simplified coordination triggers it would be possible to treat the up and downlinks completely separate by looking only at the orbital separation where there is a frequency band overlap and considering the two directions separately. For identifying possible coordination needs outside the coordination arc, there would be considerable simplification in the exchange of data between administrations, if the strapping information is not a part of the data.

If there is no change to use coordination arcs, there would be considerable simplification under the present process for both the coordination and notification phases if the two directions were treated separately. However, if there is a change to use the coordination arcs, then the benefits would only be available at the notification and recording phase of the procedures. This proposal will facilitate the work of the Bureau and administrations.

SUP EUR/13/308

Section D of Appendix S4 with some consequential modifications to Appendix S8.

2.2 Identification of networks subject to coordination

Under the present procedures, Appendix S8 (formerly Appendix 29) is used to identify the networks, with which coordination is required, but the procedures require the identification of the administrations affected and this results in some problems. Under the existing provisions in the application of No. S9.7 plus others, the BR is required to identify the administrations with which coordination is required. The trigger requirements under Appendix S8 are based on individual networks. The present practice of the BR is to stop the examination for networks of a particular administration, once one network is identified. This identified network may be an insignificant or very significant problem in the coordination process. In the publications of the BR including the Special Sections and the MR, BR only identifies the administration with no identification of the networks involved. The reasons for including an administration in the coordination requirements are not public, as the networks are not listed. When an administration receives the publication indicating that it is included in the coordination requirements for the network being published, it does not know which of its networks triggered the coordination requirement. It is then necessary for the administrations to agree on which networks will be included. Once the coordination is completed and communicated to the BR, there is no record with BR as to whether a particular network was included in the agreement or not. There are also provisions in Appendix S5 which state that no coordination is required for a modification if the interference is not increased, but BR has no record as to whether the networks were in fact coordinated in the first place.

This new approach would be equally applicable if a coordination angle is used for the trigger.

MOD EUR/13/309

S9.36 *b)* identify in accordance with No. **S9.27** any administration[13A] with which coordination may need to be effected[14];

NOTE - The subsequent footnotes in Article S9 will need to be renumbered.

ADD EUR/13/310

13A **S9.36.2** In the case of coordination under Nos. **S9.7, S9.8, S9.9, S9.12** and **S9.13**, the Bureau shall also identify the specific satellite networks that may be affected and inform administrations in the most appropriate manner.

MOD EUR/13/311

S9.41 Following receipt of the Weekly Circular referring to requests for coordination under Nos. **S9.7** to **S9.9**, an administration believing that it should have been included in the request shall, within four months of the date of publication of the relevant Weekly Circular, inform the initiating administration and the Bureau, giving its technical reasons for doing so and identifying the specific satellite networks and frequencies, and shall request that its name be included.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey

PART 7E3

PP-98 RESOLUTION 87

Role of the notifying administration

1 Background

1.1 The Plenipotentiary Conference 1998 adopted Resolution 87 dealing with the role of the Notifying Administration when acting on behalf of a group of named administrations. Under this Resolution, the Director BR is requested to prepare a report to the next WRC on this issue. During the past couple years there has been a situation in which the role and responsibility of the notifying administration when it is acting on behalf of a group of named administrations is not clear. The BR and RRB see the notifying administration as being responsible for the submission, whereas, some notifying administrations see their responsibility as that of a “post office“ and only to forward to the BR the information that they receive from the intergovernmental organization that is responsible for the satellite network. It is to be noted that under the Radio Regulations only administrations may submit notices and data to the BR for processing and also there are certain rights and obligations that flow from the application of the Radio Regulations and that these rights and obligations relate to the notifying administration. Intergovernmental satellite organizations that operate satellite networks are not recognized within the coordination and notification procedures of the Radio Regulations.

1.2 Some of the main provisions of the Radio Regulations that relate to the roles and responsibilities of the notifying administration are the following:

- S4.4 - assignment of frequencies not in conformity with the RR by an administration on the condition of no interference;
- S8.4 - recording of assignments with a reference to No. S4.4 only when the administration makes a commitment;
- S9.3 - no comments within a time period equals no objection by the administration, and administrations shall endeavour to cooperate to resolve any difficulties;
- S9.4 - the administration shall explore all possible means, etc.;
- S9.43 - an administration not responding shall be considered as not affected;
- S9.47-49 - an administration undertakes to not make a claim about harmful interference and to not cause harmful interference;
- S9.51 - an administration shall act within a specified period;

- S11.36 - undertaking by the notifying administration to not cause harmful interference;
- S11.39B - as per No. S11.36;
- Article S18 – licences.

This is only a partial listing. During the discussion at the SC, there were a number of questions raised as to which administration is responsible under the various provisions listed above. This proposal also takes note of the report of the CPM in section 7.5.3.

1.3 As for the question of licensing under Article S18, this issue is not applicable to the application of Chapter SIII of the Radio Regulations, as there is no mention of licensed stations in this chapter. Article S18 is a parallel set of obligations under the Radio Regulations and not related to the provisions of Chapter SIII. In addition some administrations do not license or are not authorized by national legislation to license the space stations for which they are the notifying administration and in the case of space stations operated by intergovernmental organizations, they are not licensed by any administration. Also the application of Article S18 is limited to private networks.

1.4 Except for Article S18 the other provisions listed in paragraph 1.2 fall into one of two categories:

- Those provisions relating to the coordination of specific earth stations with terrestrial stations or between earth stations and the provisions relating to the notification and operation of specific earth stations, it is the administration on whose territory the earth station is situated that is responsible.
- Those provisions relating to the API, coordination, notification and operations of the space station (with typical earth stations as appropriate) and in this case (for non-intergovernmental operating entities) it is the notifying administration of the space station that is responsible. In the case on intergovernmental operating entities, this is the aspect that is not clear and is being addressed in this document.

1.5 This situation of notifying on behalf of a group of administrations only applies to satellite networks and Nos. S9.1.1, No. S9.6.1 and S11.15.1 are the relevant provisions. There are no similar specific provisions in Appendices S30 and S30A, but the Rules of Procedure of the RRB (paragraph 1 under No. 4.3.5 of Appendix S30 and paragraph 1 under No. 4.2.5 of Appendix S30A) provide for such a process.

1.6 These provisions of Articles S9 and S11 clearly indicate that each administration when notifying on behalf of a group of administrations still has the right to act independently with respect to its networks. There have been cases in which the notifying administration submits notices on behalf of a group of named administration and also raises concerns about the submitted notices on the basis of its own networks. Under the provisions of the Radio Regulations it is not necessary that the same administration to be the notifying administration for all satellite networks operated by an intergovernmental organization. However, in many cases, the agreement between the intergovernmental operating organization and the host administration limits the notifying administration to the host administration.

1.7 Appendix S30B in No. 6.38 already recognizes the principle of having one of the listed administrations to be identified to act as the notifying administration.

1.8 In these cases the notifying administration normally has the responsibility to submit to the BR whatever it receives from the intergovernmental organization. Under the Radio Regulations, on the other hand, there must be a single administration that is accountable as it is impracticable for the BR or other administrations with whom coordination is required to deal with all administrations that are members of the organization or all members on whose behalf the publication is made. Normally, the present situation does not result in any problems, but in some cases, e.g. when there are questions raised or allegations of interference, etc. one administration should be responsible for investigating the case, taking the necessary action and reporting to the BR/RRB.

2 Proposals

As a consequence of the above considerations it is proposed to add to Article S7 a new provision as follows:

ADD EUR/13/312

S7.9 When an administration acts as the notifying administration of a satellite network on behalf of a group of named administrations in accordance with Nos. **S9.1.1, S9.6.1** and **S11.15.1** and Appendix **30/30A**, that administration shall act on behalf of all members of the group of administrations in the application of the various provisions of Chapter SIII of the Radio Regulations with respect to that network. In these cases it is desirable that the notifying administration be one of the members of the group on whose behalf the notification is being made.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey,

PART 7E4

PP-98 RESOLUTION 88

Processing charge for satellite networks

1 Background

The Plenipotentiary Conference 1998 adopted Resolution 88 dealing with the processing charges for satellite network filings. That Resolution included the following:

"*instructs WRC-2000*

to consider whether, in the light of the Council decisions, any relevant amendments to the Radio Regulations with respect to the procedures covered by *resolves* 2 above may be necessary,"

Council at its 1999 session adopted Decision 482 and in that decision there is the following invites WRC-2000:

"to consider, in accordance with Resolution 88 (Minneapolis, 1998), required modifications to the Radio Regulations to take account of the content of this decision,[2]

[2] The implementation of Resolution 88 (Minneapolis, 1998) implies that WRC-2000 may also consider any consequence of non-payment taking account of unforeseen circumstances, and take, in this respect, any action within its competence. In developing the required procedures, due account shall be taken of the principles contained in the Constitution and Convention, in particular those relating to the sovereign right of Member States in gaining access to spectrum and orbit resources."

One of the major concerns of many administrations is that there should be some consequences for the non-payment of the required charge within the prescribed period. For many administrations, in accordance with the decision of Council, the invoices and payments will be handled directly between the ITU and satellite network operator and therefore any consequences of non-payment should be directed towards the operator. It is recognized that there are provisions in the CS/CV, which deal with the situation of non-payments, and these are directed to the administration and deal with the non-payment of the annual contribution. There are no provisions in the CS/CV that would apply in the case of non-payment of these processing charges. As a consequence there would be no consequences resulting from non-payment unless the WRC would take such action. As the treatment of notices received by the Bureau is specified in the Radio Regulations, only a WRC can change the treatment under the Radio Regulations.

This matter was raised at the SCRPM and the CPM meeting and is treated in paragraph 7.5.4 of the CPM Report. One of the questions raised was that such a proposal could impinge on the rights of administrations. In signing the Final Acts of a WRC administrations have certain rights as well as obligations and there are many cases in which administrations rights are effected in similar manner in that the right to keep specific satellite filings/frequencies active with the ITU are subject to certain conditions such as:

- No. S9.5D in which the API publication is cancelled by the Bureau if the coordination request is not received within 24 months of the date of receipt of the API request;
- No. S11.44 in which the assignments are cancelled by the Bureau if they are not brought into use within the time period provided for by the Regulations;
- Resolution 49 (WRC-97) *resolves* 6 in which the publications are cancelled if certain specified data is not provided to the ITU within the time period specified.

In addition the Council Decision 482 in *decides* 3 specifically addresses the question of the rights of administrations in that each administration is permitted to have one satellite filing per year at no charge.

2 Proposals

As a result of the above considerations it is proposed that the following modifications be made to the Radio Regulations.

MOD EUR/13/313

S9.2B On receipt of the complete information sent under Nos. **S9.1** and **S9.2**, the Bureau shall publish[6A] it in a Special Section of its Weekly Circular within three months. When the Bureau is not in a position to comply with the time limit referred to above, it shall periodically so inform the administrations, giving the reasons therefore.

ADD EUR/13/314

[6A] **S9.2B1** If the payments are not received in accordance with the provisions of Council Decision 482 as amended on the implementation of cost recovery for satellite network filings, the Bureau shall cancel the publication and inform all administrations of such action and that the network specified in this publication no longer has to be taken into consideration by the Bureau and other administrations.

MOD EUR/13/315

S9.38 *d)* publish[14A], as appropriate, the complete information in the Weekly Circular within four months. When the Bureau is not in a position to comply with the time limit referred to above, it shall periodically so inform the administrations, giving the reasons therefore.

ADD EUR/13/316

[14A] **S9.38.1** If the payments are not received in accordance with the provisions of Council Decision 482 as amended on the implementation of cost recovery for satellite network filing, the Bureau shall cancel the publication and inform all administrations of such action and that the network specified in this publication no longer has to be taken into consideration by the Bureau and other administrations.

Modification to Appendix S30

MOD EUR/13/317

4.3.6 The Bureau shall determine on the basis of Annex 1 the administrations whose frequency assignments are considered to be affected within the meaning of § 4.3.1 or § 4.3.3. The Bureau shall include the names of those administrations with the information received under § 4.3.5.2 and shall publish[3A] the complete information in a special section of its Weekly Circular. The Bureau shall immediately send the results of its calculations to the administration proposing the modification to the appropriate Regional Plan.

ADD EUR/13/318

[3A] If the payments are not received in accordance with the provisions of Council Decision 482 as amended on the implementation of cost recovery for satellite network filing, the Bureau shall cancel the publication and inform all administrations of such action and that the network specified in this publication no longer has to be taken into consideration by the Bureau and other administrations.

Modification to Appendix S30A

MOD EUR/13/319

4.2.7 The Bureau shall determine on the basis of Annex 1 the administrations whose frequency assignments are considered to be affected within the meaning of § 4.2.1 and 4.2.3. The Bureau shall include the names of those administrations with the information received under § 4.2.6.2 and shall publish[3A] the complete information in a special section of its Weekly Circular. The Bureau shall immediately send the results of its calculations to the administration proposing the modification to the Plan.

ADD EUR/13/320

[3A] If the payments are not received in accordance with the provisions of Council Decision 482 as amended on the implementation of cost recovery for satellite network filing, the Bureau shall cancel the publication and inform all administrations of such action and that the network specified in this publication no longer has to be taken into consideration by the Bureau and other administrations.

Modification to Appendix S30B

MOD EUR/13/321

ARTICLE 6

Procedures for implementation of the Plan and regulation of the fixed-satellite service in the planned bands[1A]

ADD EUR/13/322

1A If the payments are not received in accordance with the provisions of Council Decision 482 as amended on the implementation of cost recovery for satellite network filing, the Bureau shall cancel the publication specified in Nos. 6.26, 6.33, 6.49 or cancel the entry in the list under No. 6.44 as appropriate and inform all administrations of such action and that the network specified in this publication no longer has to be taken into consideration by the Bureau and other administrations.

PART 6E

Agenda item 1.12 - Non-GSO MSS and GSO FSS at 19.3-19.7 GHz and 29.1-29.5 GHz

Introduction

Resolution 121 (WRC-97) *invites ITU-R*:

1 to undertake, as a matter of urgency, the continued development of appropriate permissible interference criteria for both non-GSO MSS feeder links and GSO FSS networks operating in the bands 19.3-19.7 GHz and 29.1-29.5 GHz;

2 to undertake, as a matter of urgency, studies of interference mitigation techniques (including those techniques listed in *considering d)*) which could facilitate coordination between non-GSO MSS feeder links and GSO FSS networks;

3 to undertake, as a matter of urgency, studies to develop coordination methodologies for GSO FSS networks and non-GSO MSS feeder links operating in the bands 19.3-19.7 GHz and 29.1-29.5 GHz on an equal basis.

The CPM Report concludes (section 6.4.2) that the requirements of Resolution 121 (Rev.WRC-97) have been satisfied and suggests that Resolution 121 (Rev.WRC-97) could now be suppressed.

This however does not take into account that no action had been taken at the time of the CPM in reponse to point 3 above. At its February 2000 meeting, WP 4A considered this issue and undertook the development of methodologies to be used under coordination involving non-GSO FSS systems, hence in particular non-GSO MSS feeder links in the 19/29 GHz bands. Although these methodologies have not at this time been fully developed, they are now expected to become part of an ITU-R recommendation within the next study period and will be used in detailed coordinations relating to this sharing situation.

ITU-R has also developed methodologies which are now included in Recommendation [Doc. 1/1004], relating to the coordination area of non-GSO FSS earth stations.

The existence of such recommendations will help in resolving a long-standing lack of harmonization in the provisions of Article S11, which results in a situation where the coexistence between GSO and non-GSO systems and between non-GSO earth stations and terrestrial stations may lead to arbitrary blockage of the recording process by a previous user of the frequency band. For this purpose, CEPT proposes that Nos. S11.32A and S11.33 also cover the possibility for the Bureau to examine notifications received from the point of view of the probability of harmful interference, using the above-mentioned methodologies.

Should WRC-2000 decide to postpone a decision on this proposal until all recommendations on this issue have been adopted by ITU-R, then Resolution 121 should be maintained. However, CEPT considers it unnecessary to delay the Conference decision on this issue and that this Resolution could therefore be suppressed.

As highlighted in section 7.5.2.7 of the CPM Report, in the cases where the coordination of an assignment under S9.7, S9.17, S9.17A and S9.18 could not be concluded successfully, Article S11 foresees a two step approach to record this assignment in the Master Register:

- In the first step, the Bureau conducts an examination of the probability of harmful interference (S11.32A for S9.7 and S11.33 for S9.17, S9.17A and S9.18). If this examination is favourable, the assignment is recorded;
- in the second step, should the examination under the first step be unfavourable, the assignment may be resubmitted and recorded if the Bureau is informed that it has been in use, together with the assignment which was the basis for the unfavourable finding, for at least four months without any complaint of harmful interference being made (S11.41). After this second step, the assignment remains under the Damocles of S11.42, i.e. any harmful interference has to be ceased if it occurs into the assignments which was the basis of the unfavourable finding.

This approach, which follows the pattern previously used under Articles 11 and 13 since 1971, ensures that an administration cannot block the recording process, hence the establishment of the rights of other administrations, for undue reasons.

This two step approach does not exist in the case where coordination under the other entry points in Article S9 could not be successfully concluded. In particular, the entry points corresponding to Resolution 46 (S9.12 to S9.16) are not covered by these provisions. This means that in case of disagreement in the coordination process under any S9.12 to S9.16, recording in the Master Register is not possible.

This is of particular concern in the case of S9.12 and S9.13 (coordination between non-GSO and GSO satellite systems) because the coordination is triggered by bandwidth overlap only, and no coordination threshold or method currently exists in these cases. This means that disagreeing to a coordination request, without any technical reason, is sufficient to prevent the access to frequencies of subsequent satellite systems (GSO or non-GSO), even if in practice no interference would occur.

Given that recommendations also exist on coordination methods relating to S9.14 (e.g. the application of the system specific methodology described in Recommendation ITU-R IS.1143 (see Annex 1 to Appendix S5) and are under development in relation to S9.11, the proposed modifications to S11 should also include a reference to these provisions.

2 Proposals

It is therefore proposed to recognize that the work undertaken by ITU-R in response to Resolution 121 (Rev.WRC-97) has been satisfactorily undertaken, hence to suppress this Resolution, and to reflect this result by harmonizing the ways in which recording is conducted under Article S11.

SUP EUR/13/371

RESOLUTION 121 (Rev.WRC-97)

Continued development of interference criteria and methodologies for fixed-satellite service coordination between feeder links of non-geostationary satellite networks in the mobile-satellite service and geostationary-satellite networks in the fixed-satellite service in the bands 19.3-19.7 GHz and 29.1-29.5 GHz

NOTE - Should WRC-2000 decide to postpone a decision on the proposals made hereafter until all Recommendations on this issue have been adopted by ITU-R, then Resolution 121 should be maintained. However, Europe considers it unnecessary to delay the Conference decision on this issue and this Resolution could therefore be suppressed.

PROPOSED MODIFICATIONS TO ARTICLE S11

MOD EUR/13/372

EUROPEAN COMMON PROPOSALS FOR THE WORK OF THE CONFERENCE

PART 6

Fixed and fixed-satellite services

CONTENTS

PART 6A

Agenda item 1.4 - Allocations and regulatory aspects related to the high-density fixed service (HDFS)

Part 6A1	Resolution 133 (WRC-97) - HDFS in the 37-39.5 GHz band
Part 6A2	Resolutions 126 and 726 (WRC-97) - HDFS in the 31.8-33.4 GHz, 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz bands
Part 6A3	Resolutions 128, 129 and 134 (WRC-97) - HDFS in the 40.5-42.5 GHz band

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Norway, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 6A1

Agenda item 1.4 - Resolution 133 (WRC-97)

HDFS in the 37-39.5 GHz band

Introduction

The 37-39.5 GHz band is presently allocated to the fixed service, the mobile service, the fixed-satellite service (downlink), and the space research service (downlink) and is already used for high-density fixed services in European countries. Therefore, the continued development of the fixed service in this band must be safeguarded.

The band is broad enough to satisfy low, medium and high-capacity fixed service needs. Recommendation ITU-R F.749-1, which provides a raster supporting all capacities, has been developed. Standardized equipment is available and is being implemented in Europe in large numbers, mainly supporting the mobile infrastructure. This HDFS use will increase with the introduction of new terrestrial mobile systems and progressive telecommunications liberalization.

These European common proposals ensure the long-term security of high-density fixed service use in the 37-39.5 GHz band by supporting:

– the use of HDFS in the 37-39.5 GHz band, and its addition in S5.547. Moreover, Europe supports the use of the band 39.5-40.5 GHz for FSS in European countries, so that both FS and FSS have the opportunity to use the 38 GHz range;

– the pfd limits defined in Option A of section 6.1.2.3.2 of the CPM Report in order to adequately protect the fixed service from FSS satellite systems;

– that the pfd limits proposed for FSS in Option A be also applied to the space research service (SRS) in the band 37.5-38 GHz and to GSO SRS in the band 37-37.5 GHz. For non-GSO SRS in the band 37-37.5 GHz, Europe proposes to keep the existing pfd mask.

ARTICLE S5

MOD EUR/13/230

34.2-40.5 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
37-37.5	FIXED MOBILE SPACE RESEARCH (space-to-Earth) MOD S5.547	
37.5-38	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE SPACE RESEARCH (space-to-Earth) Earth exploration-satellite (space-to-Earth) MOD S5.547	
38-39.5	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE Earth exploration-satellite (space-to-Earth) MOD S5.547	
39.5-40	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE MOBILE-SATELLITE (space-to-Earth) Earth exploration-satellite (space-to-Earth)	

Reasons: The fixed service is already heavily deployed in the band 37-39.5 GHz, and its use is expected to grow in the future. Insertion of footnote MOD S5.547 in this band ensures the development of HDFS, without precluding the use by other services.

MOD EUR/13/231

S5.547 The bands 31.8-33.4 GHz, 37-39.5 GHz, 40.5-42.5 GHz, 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz are available for high-density applications in the fixed service ~~(see Resolution **726 (WRC-97)**)~~. Administrations should take this into account, when considering regulatory provisions in relation to these bands.

Reasons: The fixed service is already heavily deployed in the band 37-39.5 GHz, and its use is expected to grow in the future. Resolution 726 (WRC-97) is no longer needed, because the studies leading to the identification of system characteristics of high-density systems in the fixed service in the bands listed in this Resolution have been completed. The *resolves* of Resolution 726 is also proposed to be transferred to footnote MOD S5.547.

MOD EUR/13/232

TABLE **S21-4** *(end)*

Frequency band	Service*	Limit in dB(W/m²) for angle of arrival (δ) above the horizontal plane			Reference bandwidth
		0°-5°	5°-25°	25°-90°	
31.0-31.3 GHz 31.8-32.3 GHz 34.7-35.2 GHz (space-to-Earth transmissions referred to in No. **S5.550** on the territories of countries listed in No. **S5.549**) ~~37.0~~39.5-40.5 GHz	~~Fixed-satellite~~ Mobile-satellite Space research	-115 [10]	$-115 + 0.5(\delta - 5)$ [10]	-105 [10]	1 MHz

37-40 GHz	Space research geostationary-satellite orbit Fixed-satellite geostationary-satellite orbit	-125	$-125 + (\delta - 5)$	-105	1 MHz
37.5-40 GHz	Space research non-geostationary-satellite orbit Fixed-satellite non-geostationary-satellite orbit	-120	$-120 + 0.75(\delta - 5)$	-105	1 MHz
40-40.5 GHz	Fixed-satellite	-115	$-115 + 0.5(\delta - 5)$	-105	1 MHz

Reasons: The pfd masks proposed in EUR/13/232 are needed to protect the fixed service from FSS, MSS and SRS in the band 37-40 GHz, and the FS from the SRS in the band 31.8-32.3 GHz (see EUR/13/235 to 238 for the band 31.8-33.4 GHz).

SUP EUR/13/233

RESOLUTION 133 (WRC-97)

Sharing between the fixed service and other services in the band 37-40 GHz

Reasons: Resolution 133 (WRC-97) is no longer needed, because the studies to determine pfd limits to adequately protect terrestrial services from fixed-satellite service networks have been completed, as well as the other studies leading to technical and operational recommendations to facilitate sharing between terrestrial and space services.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Croatia, Denmark, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 6A2

Agenda item 1.4 - Resolutions 126 and 726 (WRC-97)

HDFS in the 31.8-33.4 GHz, 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz bands

Introduction

Resolution 726 (WRC-97) and footnote S5.547 identify the bands 31.8-33.4 GHz, 51.4-52.6 GHz, 55.78-59 GHz and 64-66 GHz for high-density applications in the fixed service (HDFS).

HDFS meets the demand of fast growing and new applications. The recent introduction of competition in many countries has created an additional demand for narrow-band or broadband fixed wireless access to the end-user. Fixed wireless access technologies allow new operators to quickly deploy an alternative network at low cost and in a flexible way, provided that coordination and regulatory requirements are kept to a minimum. The fast growing mobile sector also increases the need for new mobile network infrastructures for GSM, GSM1800 and soon IMT-2000 operators.

The band 31.8-33.4 GHz is presently allocated to the fixed service, the radionavigation service, the space research and the inter-satellite service. However, footnote S5.547A places some constraints on these applications via Resolution 126 (WRC-97). The CPM Report concluded that the sharing between FS and the other services is feasible with some constraints. Therefore, this ECP proposes to confirm the FS allocation and to introduce the necessary pfd limits in this band.

In the band 55.78-59 GHz, sharing studies conducted in ITU-R have shown that the sharing between FS and EESS is feasible. However, in the sub-band 55.78-56.26 GHz, some limitations on the FS are necessary to ensure the sharing with the EESS. This ECP proposes to confirm the FS allocation and implement the necessary limitations in this sub-band.

In the other bands (51.4-52.6 GHz and 64-66 GHz) compatibility studies conducted within the ITU-R have shown that the sharing between HDFS and the other services is feasible.

RESOLUTION 126 (WRC-97)

Use of the frequency band 31.8-33.4 GHz for high-density systems in the fixed service

Reasons: Sharing between the space research, radionavigation and inter-satellite services is feasible as detailed in the CPM Report. Appropriate studies to determine what criteria would be necessary for sharing between stations in the fixed service and stations in the other services in this band have been conducted. The results show that the sharing is feasible with appropriate mitigation techniques. The date 1 January 2001 for the provisional application of the allocation to the fixed service in this band can be withdrawn. Reference to Resolution 126 (WRC-97) via footnote S5.547A is then no longer needed.

PART 6A3

Agenda item 1.4 - Resolutions 128, 129 and 134 (WRC-97)

HDFS in the 40.5-42.5 GHz band

Introduction

WRC-97 added a primary allocation to the fixed-satellite (space-to-Earth) service in Regions 2 and 3, and in certain non-European countries in Region 1. This allocation is subject to discussions at the next WRC, according to the resolutions mentioned above. WRC-97 also upgraded the fixed service to primary.

The band will be used in many countries including Europe to provide fixed wireless access directly to the end user for multimedia services, and such use is expected to grow in the future. Terrestrial multimedia wireless systems (MWS) have priority in Europe. The band 42.5-43.5 GHz is used by the radio astronomy service in many countries.

Europe is concerned about coexistence between MWS terminals and uncoordinated FSS and BSS earth stations in the band 40.5-42.5 GHz. Therefore, the introduction of FSS in Region 1 is opposed and the BSS allocation is proposed for deletion in Region 1. It is also proposed to introduce adequate pfd limits to protect terrestrial services from space services allocated in Regions 2 and 3, and in many countries in Region 1.

PART 6B

Agenda item 1.5 - High altitude platforms (HAPS)

1 Introduction

This proposal deals with the issues involved in the consideration of the use of HAPS in the fixed service in the 47.2-47.5 GHz and 47.9-48.2 GHz bands and in other bands in the 18-32 GHz range. Proposals concerning the use of HAPS in the IMT-2000 context are dealt with under WRC-2000 agenda item 1.6.

Since WRC-97 studies have been undertaken within ITU-R for the type of HAPS-based fixed service system described in ITU-R Recommendation [9B/TEMP/112]. For such systems the general conclusion is that co-frequency sharing in the same geographical area between HAPS-based and conventional fixed service systems could be difficult unless appropriate interference mitigation techniques are developed and implemented. The studies were based on scenarios using worst-case conditions and it has been recognized that further studies are required. As regards sharing with FSS earth stations, there are indications that small separation distances will be appropriate in some conditions but further study is required to fully assess the implications of the scenarios. It has also been concluded that it is technically feasible to protect the radio astronomy service in nearby bands through appropriate protection measures.

Consideration has been given to the use of other specific bands by HAPS-based systems in the fixed service and the CPM has noted that studies are required in respect of the use of HAPS in the fixed service within the frequency range 18-32 GHz. However, studies so far have not established a suitable basis for the sharing of use between HAPS systems in the fixed service and other services in this frequency range, in view of the current heavy usage of the spectrum. It is therefore considered premature to make any additional allocations/designations/provisions for the use of HAPS in the fixed service, or for other services (noting the comment above regarding use of HAPS in the IMT-2000 context) and further studies should be undertaken.

2 Proposal

Thus it is proposed that there should be no change in the Radio Regulations in relation to the use of HAPS in the fixed service, and that the time frame of Resolution 122 should be extended to the next WRC so that more detailed studies may be completed and that trial systems may be implemented.

3 Proposed changes to Resolution 122 (WRC-97)

Resolution 122 should be modified based on the following changes, in line with the draft text contained in the CPM Report prepared for WRC-2000.

MOD EUR/13/248

RESOLUTION 122 (Rev.WRC-~~97~~2000)

Use of the bands 47.2-47.5 GHz and 47.9-48.2 GHz by high altitude platform stations in the fixed service and by other services and the potential use of bands below 47 GHz by HAPS in the fixed service

The World Radiocommunication Conference (~~Geneva, 1997~~Istanbul, 2000),

considering

a) that the band 47.2-50.2 GHz is allocated to the fixed, mobile and fixed-satellite services on a co-primary basis;

b) that ~~this Conference has~~WRC-97 made provision for operation of high altitude platform stations, also known as stratospheric repeaters, within the fixed service in the bands 47.2-47.5 GHz and 47.9-48.2 GHz;

c) that ITU has among its purposes "to promote the extension of the benefit of the new telecommunication technologies to all the world's inhabitants" (No. 6 of the Constitution of the ITU (Geneva, 1992));

d) that systems based on new technologies using high altitude platforms will be able to provide high-capacity, competitive services to urban and rural areas;

e) that the development of any service requires major investment and that manufacturers and operators should be given the confidence to make the necessary investment;

~~e~~f) that high altitude platform systems are in an advanced stage of development and some countries have notified such systems to ITU;

~~f~~g) that the Radio Regulations Board issued a provisional rule of procedure concerning notification periods in No. **S11.24/1228** in February 1997;

~~g~~h) that in spite of the urgency attached to the development of such systems, technical, sharing and regulatory issues should be further studied in order to achieve the most efficient use of the spectrum available for these systems;

~~h~~i) that technical studies ~~are required in order to ascertain the extent to which sharing of the~~have been undertaken on the characteristics of a HAPS system in the frequency bands 47.2-47.5 GHz and 47.9-48.2 GHz ~~is feasible between systems using high altitude platforms in the fixed service and systems in the fixed, fixed-satellite and mobile services, and to ascertain the requirements to protect radio astronomy services in adjacent bands from spurious emissions~~and on the coordination and sharing requirements between HAPS systems and systems in the conventional fixed service and in other services, but that further studies are still in progress on the potential for interference between such systems;

~~i~~j) that the radio astronomy service has primary allocations in the bands 42.5-43.5 GHz and 48.94-49.04 GHz;

~~*j)* that ITU-R studies are already under way on the preferred characteristics of systems using high altitude platforms and the feasibility of sharing between these systems and systems of other services and between these systems and other systems in the fixed service (Questions ITU-R 212/9, ITU-R 218/9 and ITU-R 251/4);~~

k) that ITU-R study results have been presented which indicate that in WRC-97 designated bands at 47.2-47.5/47.9-48.2 GHz, sharing between fixed service systems using HAPS and other conventional fixed service systems in the same area will require appropriate interference mitigation techniques to be developed and implemented;

~~k~~l) that No. **S5.552** urges administrations to reserve fixed-satellite service use of the band 47.2-49.2 GHz for feeder links for the broadcasting-satellite service, and that~~ preliminary~~ ITU-R studies indicate that high altitude platform stations in the fixed service may share with broadcasting-satellite feeder links;

~~*l)* that the development of services using high altitude platform stations in these bands requires major investment and that manufacturers and operators should be given the confidence to make the necessary investment in these applications,~~

m) that ITU-R studies in the bands 47.2-47.5 GHz and 47.9-48.2 GHz indicate that sharing between fixed service systems using HAPS and FSS could be feasible under certain limitations, such as geographical separation between HAPS-based systems and FSS earth stations;

n) that since 47 GHz bands are more susceptible to the rain attenuation in certain areas of Region 3, the range 18-32 GHz has been proposed for possible identification of additional spectrum in ITU-R and preliminary studies are in progress for these bands;

o) that the 18-32 GHz range is already heavily used by a number of different services,

resolves

1 to urge administrations to facilitate coordination between high altitude platform stations in the fixed service operating in the bands 47.2-47.5 GHz and 47.9-48.2 GHz and other co-primary services in their territory and adjacent territories;

2 that, on a provisional basis, the procedures of Article **S9** shall be used for coordination between satellite systems and high altitude platform systems;

3 to request ITU-R to continue to carry out urgently studies on the appropriate technical sharing criteria for the situations referred to in *considering ~~h~~i)*~~, with priority given to the sharing with other systems in the fixed and fixed-satellite services, in particular the determination of the appropriate geographical separation from feeder links in the broadcasting-satellite service~~;

4 to request ITU-R, taking into account the requirements of other fixed service systems and other services, to urgently conduct studies on the feasibility of identifying additional frequencies for the use of HAPS in the fixed service in the range 18-32 GHz;

~~4~~5 that WRC-~~99~~02 should review the results of these studies and consider refinement of the regulatory provisions that might facilitate a broader application of these high altitude platform technologies,

instructs the Director of the Radiocommunication Bureau

1 that notices concerning high altitude platform stations that were received by the Bureau prior to 22 November 1997, and provisionally recorded in the Master International Frequency Register in accordance with the provisional rule of procedure issued by the Board, shall be maintained;

2 that from 22 November 1997, and pending review of the sharing studies in *considering ~~h~~i)* and review of the notification process by WRC-~~99~~02, the Bureau shall accept notices in the bands 47.2-47.5 GHz and 47.9-48.2 GHz only for high altitude platform stations in the fixed service and for feeder links for the broadcasting-satellite service, shall continue to process notices for fixed-satellite service networks (except for feeder links for the broadcasting-satellite service) for which complete information for advance publication has been received prior to 27 October 1997, and shall inform the notifying administrations accordingly.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 6C

Agenda item 1.8 - Earth stations on board vessels in the FSS at 3 700-4 200 MHz and 5 925-6 425 MHz

Introduction

Agenda item 1.8 requests to consider regulatory and technical provisions to enable earth stations located on board vessels (ESV) to operate in the fixed-satellite service (FSS) networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz, including their coordination with other services allocated in these bands.

Both bands are heavily used by the fixed service throughout Europe and significant growth is expected in the future, in order to satisfy the fixed service spectrum requirements for long-haul high capacity systems which could not be accommodated in other bands.

The ESV operation bears a great potential of interference to the fixed service applications in the 5 925-6 425 MHz and could constraint the fixed service development in the 3 700-4 200 MHz if protection from the FS were to be requested. Therefore, a change to the Radio Regulations which would permit use of ESVs could not be supported if it had the potential to allow harmful interference to the fixed service, or if it introduced additional constraints on the development of the fixed service.

Considering that the studies of the technical and regulatory environment of the use of the ESV have not been completed within ITU-R, Europe proposes to make no change to the existing Radio Regulations and that further studies be conducted to resolve the technical, regulatory and legal uncertainties before a future possible recognition of the ESV in the Radio Regulations.

ADD EUR/13/251

RESOLUTION [EUR/13/8] (WRC-2000)

Feasibility studies into the operations of earth stations located on board vessels using fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that there is a demand for global wideband satellite communication services on vessels;

b) that the technology exists that would permit the use of fixed-satellite services (FSS) networks by earth stations on board vessels (ESV) operating in the 3 700-4 200 MHz and 5 925-6 425 MHz bands;

c) that ESV have the potential to cause unacceptable interference to the fixed service (FS) systems in the band 5 925-6 425 MHz;

d) that in order to ensure the protection and future growth of the FS, the ESV would have to operate with certain technical and operational constraints;

e) that ESV shall not claim protection from fixed service station transmissions;

f) that administrations may authorize radiocommunication stations on off-shore structures and platforms for which they are responsible,

noting

a) that operation within the territorial sea is at the discretion of the administration with territorial authority, in which case the relevant procedures of that administration will apply;

b) that operation of earth stations on board vessels from specified fixed points at locations outside the territorial sea but for which an administration has territorial jurisdiction would be fully within the FSS,

recognizing

that studies within ITU-R have not been completed,

resolves

1 to request ITU-R to continue to study, as a matter of urgency, the regulatory, technical and operational constraints to be applied to ESV operations and, in particular, to determine the appropriate value for the operational minimum distance from the territory of an administration beyond which ESV are assumed not to have the potential to cause unacceptable interference to the fixed service stations of that administration;

2 that WRC-03 should review the results of these studies to consider whether earth stations located on board vessels could operate in fixed-satellite service networks in the bands 3 700-4 200 MHz and 5 925-6 425 MHz,

requests the Secretary-General

to send this Resolution to the Secretary-General of the International Maritime Organization (IMO).

Reasons: To request ITU-R to further study the technical, regulatory and legal issues regarding ESV operations before a future possible recognition of the ESV in the Radio Regulations.

PART 6D

Agenda item 1.14 - Non-GSO MSS feeder links in the 15.43-15.63 GHz band

Introduction

WRC-95 and WRC-97 allocated the frequency band 15.43-15.63 GHz to the fixed-satellite service (space-to-Earth) on a primary basis, limited to non-GSO MSS feeder links. RR No. S5.511A specifies that "... in the space-to-Earth direction, harmful interference shall not be caused to stations of the radio astronomy service using the band 15.35-15.4 GHz." Furthermore the frequency band 15.35-15.4 GHz is allocated on a primary basis to the Earth exploration-satellite (passive) and space research (passive) services.

Based on Resolution 123 (WRC-97) the World Radiocommunication Conference 2000 (WRC-2000) has to discuss issues related to the allocation to the fixed-satellite service (FSS) (space-to-Earth) to provide feeder links to non-geostationary-satellite orbit (non-GSO) mobile-satellite service (MSS) systems in the band 15.43-15.63 GHz.

ITU-R studies have shown that there is no need to modify the current allocation to the fixed-satellite service (FSS) (space-to-Earth) as presented in RR Article 5. However No. S5.511A should be modified to state that operation of FSS in the band 15.43-15.63 GHz (space-to-Earth) should be limited to non-GSO MSS feeder links for which advanced publication information has been received by the Bureau prior to the end of WRC-2000.

There is also a need to clarify the provisions of S5.511A so that the limits that need to be met to ensure protection of the radio astronomy service are clearly indicated and that compliance with these limits can be the subject of a finding by the Radiocommunication Bureau. The use of incorporation by reference in this situation is not considered appropriate.

On these bases, it is also proposed that Resolution 123 (WRC-97) be suppressed.

Proposed modifications to Article S5

MOD EUR/13/252

14.25-15.63 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
15.43-15.63	FIXED-SATELLITE (space-to-Earth) (Earth-to-space) MOD S5.511A AERONAUTICAL RADIONAVIGATION S5.511C	

MOD EUR/13/253

S5.511A Use of the band 15.43-15.63 GHz by the fixed-satellite service (space-to-Earth ~~(see Resolution **123 (WRC-97)**)~~ and Earth-to-space) is limited to feeder links of non-geostationary systems in the mobile-satellite service, subject to coordination under No. **S9.11A**. The use of the frequency band 15.43-15.63 GHz by the fixed-satellite service (space-to-Earth) is limited to non-GSO MSS feeder-link systems for which advanced publication information has been received by the Bureau prior to the end of WRC-2000. In the space-to-Earth direction, the minimum earth station elevation angle above and gain towards the local horizontal plane and the minimum coordination distances to protect an earth station from harmful interference shall be in accordance with Recommendation ITU-R S.1341. ~~Also in the space-to-Earth direction, harmful interference shall not be caused to stations of the radio astronomy service using the band 15.35-15.4 GHz. The threshold levels of interference and associated power flux-density limits which are detrimental to the radio astronomy service are given in Recommendation ITU-R RA.769-1. Special measures will need to be employed~~In order to protect the radio astronomy service in the band 15.35-15.4 GHz, the aggregate power flux-density radiated in the 15.35-15.4 GHz band by all the space stations within any non-GSO MSS feeder link (space-to-Earth) system operating in the 15.43-15.63 GHz band shall not exceed the level of –156 dB(W/m^2) in a 50 MHz bandwidth into any radio astronomy observatory site for more than 2% of the time.

Reasons: The ITU-R studies in requirements for allocating the frequency band 15.43-15.63 GHz (space-to-Earth) to non-GSO MSS feeder links confirmed the importance and demand in the frequency spectrum resource of an allocation in the band 15.43-15.63 GHz (space-to-Earth).

Studies on the feasibility of providing protection from interference to the radio astronomy, Earth exploration-satellite (passive) and space research (passive) services operating in the band 15.35-15.4 GHz showed that non-GSO MSS feeder-link systems for which advance publication has already been received by the Bureau in the frequency band 15.43-15.63 GHz (space-to-Earth) could provide sufficient protection to the radio astronomy, Earth exploration-satellite (passive) and space research (passive) services.

The level of protection considered sufficient for radio astronomy and that can be met by these non-GSO MSS feeder-link systems corresponds to not exceeding for more than 2% of the time the level of detrimental interference set forth in Recommendation ITU-R RA.769-1, i.e. a level of –156 dB(W/m^2) in any 50 MHz bandwidth for the aggregate pfd radiated by all the space stations in the non-GSO MSS feeder link system at the radio astronomy observatory site.

However, future non-GSO MSS systems using the 15.43-15.63 GHz space-to-Earth allocation would have to use substantial mitigation techniques to adequately protect the radio astronomy service operating in the band 15.35-15.4 GHz from harmful interference.

SUP EUR/13/254

RESOLUTION 123 (WRC-97)

Feasibility of implementing feeder links of non-geostationary satellite networks in the mobile-satellite service in the band 15.43-15.63 GHz (space-to-Earth) while taking into account the protection of the radio astronomy service, the Earth exploration-satellite (passive) service and the space research (passive) service in the band 15.35-15.4 GHz

Reasons: In the case WRC-2000 decides to implement the above-mentioned proposals, there would be no need for further studies to protect the radio astronomy in this band.

PART 5A

Agenda item 1.19*bis* - Scope of the ROP on S23.13

Introduction

In response to Resolution 531 (WRC-95), the RRB established a Rule of Procedure on S23.13 in 1996 which was later modified in 1998. If the service area of a BSS system exceeds the territory of the notifying administration, the Rule of Procedure requires that a separate agreement from the one required under Article 4 of Appendix S30 or Resolution 33 (Rev.WRC-97) be sought either directly from the administrations concerned or through the publication required under Resolution 33 (Rev.WRC-97) or the plan modification procedure.

The above-mentioned administrations consider that this Rule of Procedure should not be applied retroactively to systems received by the BR for the application of Article 4 of Appendix S30 before 18 November 1995.

EUR/13/196

Consequently, it is proposed that no specific action be taken by WRC-2000 on this agenda item.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 5B

PART 5B1

Agenda item 1.20 - Procedures for the use of the guardbands of Appendices S30 and S30A Plans to perform space operations functions, also taking into account Resolution 86 (Minneapolis, 1998)

Introduction

The lack of a coordination procedure and criteria relating to the use of the guardbands of the BSS and associated feeder-link Plans to perform space operation functions was pointed out during WRC-95.

CPM99-2 noted that ITU-R had developed criteria that could be used in applying the procedures of Article S9 or Appendices S30 and S30A in this context and concluded that a possible way to apply these procedures in this context would be to coordinate such use using the same procedures as those applicable to non-planned services in the bands covered by these Appendices, specifically:

- to coordinate this use with the assignments subject to the Plan using Article 7 of Appendix S30 or No. S9.8 and Article 7 of Appendix S30A or No. S9.9, as appropriate;
- to coordinate this use with the assignments in non-planned services, and vice versa, using the provisions of Articles S9/S11;
- to coordinate modifications to the Plans with such use using paragraph 4.3.1.5 or 4.3.3.5, as appropriate, of Article 4 of Appendix S30, and using paragraph 4.2.3.x of Article 4 of Appendix S30A (see section 5.2.3 for details on this possible additional provision).

Europe supports the approach proposed by the CPM on this issue and, in line with the CPM conclusions, proposes that this approach be implemented as follows. In line with Part 2, the following proposals are based on Approach B described in Chapter 5 of the CPM Report (i.e. the current Articles 6 and 7 of Appendices S30 and S30A are suppressed and replaced by S9.8, S9.9, S9.19 and the associated provisions in Appendix S5 and Article S11).

It is proposed to include the following two additional footnotes in the title of Article S9.

MOD EUR/13/197

ARTICLE S9

Procedure for effecting coordination with or obtaining agreement of other administrations[1, 2, 3, 4, 5, 6, 7]

ADD EUR/13/198

---

[6] **A.S9.6** The use of the guardbands of the Plans in Appendix **S30**, as defined in section 3.9 of Annex 5 to this Appendix, to provide space operations functions in accordance with No. **S1.23** shall be coordinated with the assignments subject to these Plans using the provisions of No. **S9.8**. Coordination among assignments intended to provide these functions and services not subject to a Plan shall be effected using the provisions of No. **S9.7** and the associated provisions of Articles **S9** and **S11**. Coordination of modifications to the Plans with assignments intended to provide these functions shall be effected using paragraph 4.3.1.5 or 4.3.3.5, as appropriate, of Article 4 of Appendix **S30**, considering, for this purpose, that space operations functions are operating in the fixed-satellite service.

ADD EUR/13/199

---

[7] **A.S9.7** The use of the guardbands of the Plans in Appendix **S30A**, as defined in sections 3.1 and 4.1 of Annex 3 to this Appendix, to provide space operations functions in accordance with No. **S1.23** shall be coordinated with the assignments subject to these Plans using the provisions of No. **S9.9**. Coordination among assignments intended to provide these functions and services not subject to a Plan shall be effected using the provisions of No. **S9.7** and the associated provisions of Articles **S9** and **S11**. Coordination of modifications to the Plans with assignments intended to provide these functions shall be effected using paragraph 4.2.1.2A of Article 4 of Appendix **S30A**.

The coordination criteria applicable in the above procedures would be equally applicable to the situations involving space operations functions in the guardbands of the Plans.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 5B2

Agenda item 1.20 - Proposed revisions relating to the suppression of Articles 6 and 7 of Appendices S30 and S30A, also taking into account Resolution 86 (Minneapolis, 1998)

1 Introduction

Europe supports the conclusions reported in Chapter 5 of the CPM Report taking into account Resolution 86 (Minneapolis, 1998) and considers of primary importance, for the conservation of the Appendices S30 and S30A Plans and the protection of other non-planned services and systems in the frequency bands covered by these Plans, that the deficiencies identified by the CPM regarding the existing provisions relating to the coordination between planned and non-planned services be corrected as a matter of urgency.

Concerning the approach to be selected in response to agenda item 1.20, the CPM identified three possible approaches. Europe considers that Approach B, under which Articles 6 and 7 of Appendices S30 and S30A are suppressed and replaced by the equivalent procedures under Articles S9 and S11 and Appendix S5, is clearly preferable to the other approaches identified in the CPM Report to satisfy the agenda item, for the following reasons:

a) It is the only approach consistent with the decisions taken by WRC-95 and WRC-97 on the simplification of the Radio Regulations and with the intent of Resolution 86 (Minneapolis, 1998), "to achieve additional simplification and cost savings for the Radiocommunication Bureau and administrations".

b) As highlighted by the examples of possible modifications given in Annex 1 to Chapter 5 of the CPM Report, Approach A would lead to a number of extensive changes in the current procedures of Appendices S30 and S30A, and to unduly complicated modifications to the current procedures in Article S9 and associated Appendix S5, with the only result of a duplication of extensive regulatory text.

c) Under Approach A, many sections remained to be reviewed in order to be aligned with the current practice as contained in S11.49, which is not necessary under Approach B.

d) Although Approach C has the potential for even greater simplicity, additional study would be required on this Approach prior to its possible consideration by WRC-2000.

2 Description of the proposed approach

The proposed Approach (Approach B in Chapter 5 of the CPM Report) consists in suppressing Articles 6 and 7 of Appendices S30 and S30A and replacing them by currently existing or suspended provisions under Articles S9 and S11 and under Appendix S5. In order to correct the deficiencies identified by the CPM, modifications to these provisions and to some provisions under Appendix S30 are also proposed.

In summary, the proposed Approach consists in the following:

- Article 6 of Appendix S30 is suppressed and replaced by S9.19. In this context, there would be a need to update Annex 3 of Appendix S30, which contains the associated method for the determination of the need for coordination, to include the case of interference caused by transmit FSS earth stations, and to take into account the results of the studies recently carried out in ITU-R on this type of interference in the framework of the revision of Appendix S7.
- Article 7 of Appendix S30 is suppressed and replaced by S9.8. Annex 4 of Appendix S30, which contains the associated method for the determination of the need for coordination, is moved to Appendix S5, where it is already referred to.
- Article 6 of Appendix S30A is suppressed. Consequential to the use of S9.17 and S9.17A proposed in section 3 below instead of Article 4 of Appendix S30A for the coordination of feeder-link earth stations with terrestrial stations or with earth stations operating in the opposite direction of transmission, this provision is no longer necessary.
- Article 7 of Appendix S30A is suppressed. Section 7.1 of this Article is replaced by S9.9. Section 1 of Annex 4 of Appendix S30A, which contains the associated method for the determination of the need for coordination, is moved to Appendix S5, where it already appears. Section 7.2 of this Article is replaced by S9.17A. Section 3 of Annex 4 of Appendix S30A, which contains the associated method for the determination of the need for coordination, is moved to Appendix S7, as proposed by the CPM.

3 Proposed modifications to the Radio Regulations to correct the deficiencies identified by the CPM in respect of the provisions of Appendices S30 and S30A

In the framework of Resolution 86 of the Plenipotentiary Conference (Minneapolis, 1998), the current situation of the relevant procedures of Article S9 and Articles 4, 6 and 7 of Appendices S30 and S30A was analysed by the CPM with regard to the two following principles:

1) all possible cases of interference that may arise in practice between planned BSS and non-planned services (e.g. FSS or FS) should be covered by a procedure;

2) the coordination between earth stations and terrestrial stations, and between earth stations operating in opposite directions of transmission should be undertaken by and between the administrations on the territory of which these stations are located.

Europe supports the conclusions reached by the CPM under this agenda item and considers of primary importance, for the conservation of the Appendices S30 and S30A Plans and the protection of other non-planned services and systems in the frequency bands covered by these Plans, that the deficiencies identified by the CPM regarding the existing provisions relating to the coordination between planned and non-planned services be corrected as a matter of urgency.

In the framework of the proposed Approach outlined in the previous section, the following proposals are made to correct these deficiencies:

3.1 To avoid the inclusion in the Plans in the Master Register of mutually incompatible assignments, it is proposed to modify section 1 of Appendix S5 in order to allow the inclusion in the coordination process under S9.8 and S9.9 of assignments for which a modification to one of the BSS Plans in Appendices S30 and S30A has been initiated, but not yet completed.

3.2 To enable receive BSS earth stations to be protected from FSS transmit earth stations operating in opposite directions of transmission (e.g. in the frequency band 12.5-12.7 GHz which is allocated to planned BSS in Region 2 and to FSS Earth-to-space in Region 1), it is proposed, as in the example provided by the CPM under Annex 2 of Chapter 5, to extend the scope of S9.19 to cover this case.

3.3 The use of S9.17A and S9.19 (as modified under 3.2 above) allows the coordination between earth stations and terrestrial stations, and between earth stations operating in opposite directions of transmission to be handled between the administrations on the territory of which these stations are located, and is therefore in line with Resolution 1 (Rev.WRC-97). No further change is therefore required to correct the current deficiency in Appendices S30 and S30A. This corresponds to Option C in subsection e) of section 5.2.3.2.1 of the CPM Report.

3.4 In order to enable the coordination of planned feeder-link earth stations with terrestrial stations while conforming to Resolution 1 (Rev.WRC-97), the solution proposed in section 5.2.3.2.3 of the CPM Report is proposed, which consists in replacing paragraphs 4.2.1.3 and 4.2.3.3 of Article 4 of Appendix S30A by No. S9.17.

3.5 Similarly, in order to enable the coordination of planned feeder-link earth stations with earth stations operating in the opposite direction of transmission while conforming to Resolution 1 (Rev.WRC-97), the solution proposed in section 5.2.3.2.4 of the CPM Report is proposed, which consists in replacing paragraphs 4.2.1.2/4.2.3.2 of Article 4 of Appendix S30A by No. S9.17A.

3.6 As outlined in section 5.2.3.3.1 of the CPM Report and to enable the coordination of non-planned BSS with planned BSS in the frequency band 12.5-12.7 GHz, where BSS is planned in Region 2 and non-planned in Region 3, it is proposed to replace the terms "fixed-satellite service" by "fixed-satellite service or broadcasting-satellite service where these services are not subject to a Plan" in No. S9.8 and Appendix S5. The Criteria of Annex 4 of Appendix S30 are proposed to be used to determine if the coordination is required.

3.7 As outlined in section 5.2.3.3.2 of the CPM Report and to enable the coordination between non-planned and Planned BSS feeder links in the 17.8-18.1 GHz band, it is proposed to:

a) under Article 4 of Appendix S30A, the inclusion of an additional paragraph in order to protect Region 2 non-planned FSS (Earth-to-space) from modifications to the Regions 1 and 3 feeder-link Plan;

b) in No. S9.9, the suppression of the term "space", in "transmitting space station in the FSS", in such a way that the procedure would cover the interference caused by either an FSS space station or an FSS earth station.

In both cases, it is proposed that the criteria to determine if the coordination is required be aligned with those of Annexes 1 and 4 of Appendix S30A, i.e. a delta T/T criterion. Noting that a value of 4% appears for this criterion in Annex 4 of Appendix S30A to protect the BSS feeder-link space station from a transmit FSS space station, it is proposed to use the same value when the interference is caused by a transmit BSS feeder-link earth station.

It should be noted that section 1 of Annex 4 of Appendix S30A contains thresholds to determine the need for coordination between non-planned FSS or BSS transmit space stations in the 17.3-18.1 GHz band. These thresholds are a combination of a delta T/T method (4%) and pfd limits, depending on the orbital separation with space stations in the Plan. This dual criterion does not appear to adequately protect the Plan (if the pfd value provides more protection that the delta T/T for the corresponding orbital separations, it is overly protective; if it provides less protection, it does not protect the Plan; if it provides the same protection, it is introduces an unnecessary complexity). It is therefore proposed that only the criterion of a 4% delta T/T be retained in this case.

3.8 As outlined in section 5.2.3.3.3 of the CPM Report, in order to enable the coordination of non-planned BSS transmit space stations in the frequency band 17.3-17.8 GHz with the Appendix S30A Plan, it is proposed to replace the words "station in the FSS" in No. S9.9 by "station in the FSS or in the BSS".

3.9 Section 5.2.3.3.4 of the CPM Report outlines the need to enable the protection of non-planned BSS receive earth stations in Region 2 from modifications to the BSS feeder-link Plan in the band 17.3-17.8 GHz band. Under the proposed approach, this protection is already covered under S9.19.

3.10 Associated with the proposed use of S9.19 to protect the BSS service area from interference caused by terrestrial stations or earth stations in the opposite direction of transmission, it is proposed that consideration be given to modify the method of Annex 3 of Appendix S30, taking advantage of the work performed in ITU-R on the revision of Appendix S7. This would have the clear advantage of benefiting from the results of the most recent ITU-R studies in propagation and system characteristics. In contrast, the method of Annex 3 of Appendix S30, which was not updated since 1977 for Regions 1 and 3, contains major inconsistencies with respect to the calculation of the interfering levels. It also has the major disadvantage of not taking into account the elevation of the horizon around the interfering station, which is an unrealistic assumption.

4 Detailed proposals

On the basis of the potential solutions described in the CPM Report and recalled in the previous sections to correct the deficiencies identified in the current procedures of Article S9 and Appendices S30 and S30A in relation to the coordination between planned and non-planned services, this section contains proposals for regulatory text that would reflect these solutions by modifications or additions to the current provisions of Article S9 and the associated provisions in Appendix S5, and in Appendices S30 and S30A. These proposals are based on the replacement of Articles 6 and 7 of Appendices S30 and S30A by these provisions and the suppression of these Articles ("Approach B").

Proposed modifications to Article S9

Sub-Section IIA – Requirement and request for coordination

NOC

S9.6 to S9.7

MOD EUR/13/200

S9.8 *b)*~~[12]~~ for a transmitting space station~~ of the fixed-satellite service~~ using the geostationary-satellite orbit, in the fixed-satellite service or in the broadcasting-satellite service, in a frequency band ~~shared on an equal primary basis with the broadcasting-satellite service,~~and in a Region where this service is not subject to a Plan, in respect of stations ~~of the latter service~~in the broadcasting-satellite service which are subject to the Appendix **S30** Plans;

Reasons: Cover the case of non-planned interfering into the Plan or its modifications. This provision would replace Article 7 of Appendix S30.

MOD EUR/13/201

S9.9 *c)*~~[12]~~ for a transmitting~~ space~~ station ~~of~~in the fixed-satellite service or in the broadcasting-satellite service using the geostationary-satellite orbit in a frequency band ~~shared on an equal primary basis with the feeder links of~~and in a Region where this service is not subject to a Plan, in respect of a receiving feeder-link space station for the broadcasting-satellite service which are subject to the Appendix **S30A** Plans;

Reasons: Cover the case of interference into Appendix S30A Plan from non-planned BSS in Region 2 (17.3-17.8 GHz) and from non-planned feeder links in Region 2 (17.8-18.1 GHz). This provision would replace section 7.1 of Article 7 of Appendix S30A.

MOD EUR/13/202

S9.17 *f)*~~[13]~~ for any specific earth station or typical mobile earth station in frequency bands above 1 GHz allocated with equal rights to space and terrestrial services, in respect of terrestrial stations, where the coordination area of the earth station includes the territory of another country, with the exception of the coordination under No. **S9.15**;

~~[12] **S9.8.1** and **S9.9.1** Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.~~

Reasons: As a consequence of the proposed changes, S9.8, S9.9, S9.17A and S9.19 and the associated provisions in Appendix S5 and Article S11 effectively replace Articles 6 and 7 of Appendices S30 and S30A procedures by equivalent provisions, hence the suspension of these provisions is no longer necessary.

~~[13] **S9.17.1** Application of this provision with respect to Articles 6 and 7 of Appendices **S30** and **S30A** is suspended pending a decision of WRC-99 on the revision of these two Appendices.~~

Reasons: As a consequence of the proposed changes, S9.8, S9.9, S9.17A and S9.19 and the associated provisions in Appendix S5 and Article S11 effectively replace Articles 6 and 7 of Appendices S30 and S30A procedures by equivalent provisions, hence the suspension of these provisions is no longer necessary.

MOD EUR/13/203

S9.17A *g)* for any specific earth station, in respect of other earth stations operating in the opposite direction of transmission, in frequency bands allocated with equal rights to space radiocommunication services in both directions of transmission and where the coordination area of the earth station includes the territory of another country or the earth station is located within the coordination area of another earth station~~, with the exception of the frequency bands subject to the Appendix **S30A** Plans~~with the exception of the coordination under No. **S9.19**;

Reasons: This coordination must be undertaken by the administration on the territory of which the earth stations are located, which is not the case in Article 4 or in Article 7 of Appendix S30A. The words deleted were introduced by WRC-97 in order to avoid any unintended consequences. Their suppression would allow to replace both Nos. 4.2.1.2/4.2.3.2 of Article 4 of Appendix S30A and section 7.2 of Article 7 of Appendix S30A. The proposed addition to except coordination under S9.19 is to allow S9.19 to ensure the protection of the BSS service area from interference caused by earth stations operating in the opposite direction of transmission. In contrast, S9.17A only applies to protect specific earth stations.

NOC S9.18

MOD EUR/13/204

S9.19 *i)* for any transmitting station of a terrestrial service or a transmitting earth station in the fixed-satellite service (Earth-to-space) in a frequency band shared on an equal primary basis with the broadcasting-satellite service, with respect to a~~n~~ typical earth station within the service area of a space station in the broadcasting-satellite service~~, except where this service is subject to the Appendix **S30** Plans~~;

Reasons: The first proposed addition is to ensure the protection of the BSS service area from interference caused by earth stations operating in the opposite direction of transmission (S9.17A, which only applies to protect specific earth stations, could not readily achieve this). The second addition is to clarify that this provision is intended to protect the BSS service area. The proposed deletion ensures that S9.19 effectively replaces Article 6 of Appendix S30. The use of S9.19 also allows, without requiring any additional provision, that this coordination be undertaken by the administrations on the territory of which the earth stations and/or terrestrial stations are located, in line with Resolution 1 (Rev.WRC-97).

Proposed modifications to Appendix S5

APPENDIX S5

Identification of administrations with which coordination is to be effected or agreement sought under the provisions of Article S9

PART 4A

Agenda item 1.16 - Allocation of frequency bands above 71 GHz to the Earth exploration-satellite (passive) and radio astronomy services, taking into account Resolution 723 (WRC-97)

Introduction

During WRC-97, work on the allocation above 71 GHz to science services could not be completed, as studies had not yet fully finished; therefore WRC-97 decided to reconsider these allocations once more at WRC-2000 (see Resolution 723 (WRC-97)).

The present RR Table of Frequency Allocations with regard to frequencies above 71 GHz, adopted during WARC-79, does not any more correspond fully to the needs of the Earth exploration-satellite service (EESS), the space research service (SR) and the radio astronomy service (RA). Considerable progress has been made in this science area, resulting in the situation that the ITU Table of Frequency Allocations needs to be adapted to modern needs.

The following general principles for the revision of the Table of Frequency Allocations above 71 GHz are the basis for the review of the Table of Frequency Allocations:

- the allocations to the passive services should be in response to physical processes in space or the atmosphere;
- passive sensors of the EESS are operated on a global basis, and coordination with other services is not practical. The only sharing possibility resides in a strict compliance with the interference threshold of the passive sensors;
- no satellite downlinks within important RA bands or within bands adjacent to those in which an allocation for radio astronomy is foreseen;
- co-allocation of RA and terrestrial services (except high altitude platforms) is possible, provided there is the necessary coordination around the radio astronomy station; (The number of mm-wave observatories worldwide is expected to remain very limited, because, *inter alia*, few sites on Earth fulfil the stringent requirements that justify the required investment. Locations of mm-wave radio observatories are selected mostly on the basis of low water vapour content of the atmosphere, and stability of the climate. Preferred locations are, therefore, high mountain tops or plateaux in a desert environment, far from major cities and centres of urbanization. Therefore, this service will be able to share its frequency bands with terrestrial services). See also Article S29;

- there should be, wherever possible, no difference between the total amount of frequency spectrum allocated to the various services in the present Radio Regulations, and the total amount of frequency spectrum after the rearrangements, except for those allocations, subject to the agenda item 1.16; however, this principle should not be applied at the expense of the usability of spectrum for the individual services allocated to a band due to protection requirements or interference from other allocated services. Thus, unfavourable combinations of allocations in a band should be avoided;
- wherever there are conflicts between requirements from the different services, the services with a justified need for that specific band will have priority over the others. The other service(s) will then be reallocated to other bands taking into account general spectrum requirements of the different services. (Although most of the active radio services are not about to utilize the frequency bands above 71 GHz in the immediate future, adequate spectrum resources must be provided to allow for the development of radio equipment);
- taking due account of the convergence of the fixed and mobile services, these two services could have a co-allocation in various frequency bands concerned, although convergence may not take place in all co-allocated bands;
- primary allocations should be mentioned in the Table of Frequency Allocations itself, not in footnotes to the table.
- the above-mentioned countries propose to use this review of the allocations to passive services above 71 GHz, for inclusion of allocations to the EESS (active) in the band 130-130.5 GHz (for high accuracy altimetry) and to the EESS (active) and SR (active) in the band 237.9-238 GHz (for spaceborne cloud radars).

Noting that the provisional agenda for WRC-02/3 includes agenda item 3 (results of studies with a view to consider for inclusion in a future agenda: .... 3.2 allocations above 275 GHz), it is concluded that the proposal to WRC-2000 shall be limited to frequency bands below 275 GHz.

The best way to proceed at this Conference with views for the spectrum above 275 GHz is to extend the Table of Frequency Allocations to 1 000 GHz in order to allow the indication in footnote S5.565 that certain frequency bands in this range are of interest for the science services.

Annex 1A gives a comprehensive overview of the totals of primary allocations within the current Article S5 of the Radio Regulations for the range above 71 GHz; Annex 1B gives such an overview for the newly proposed Table of Frequency Allocations, as well as a comparison between the total amount of allocations in the current and newly proposed Radio Regulations.

Annex 2 specifies the European common proposal in detail.

ANNEX 1A

Summary table of primary allocations in the current RR: 71-275 GHz

ANNEX 2

European common proposals for agenda item 1.16

MOD EUR/13/154

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
71-74	FIXED FIXED-SATELLITE (~~Earth-to-space~~space-to-Earth) MOBILE MOBILE-SATELLITE (~~Earth-to-space~~space-to-Earth) ~~S5.149 S5.556~~	
74-~~75.5~~76	~~AMATEUR~~ ~~AMATEUR-SATELLITE~~ BROADCASTING-SATELLITE FIXED FIXED-SATELLITE (~~Earth-to-space~~space-to-Earth) MOBILE Space research (space-to-Earth) MOD S5.561 ADD S5.EEE	
76-~~81~~77.5	RADIO ASTRONOMY RADIOLOCATION Amateur Amateur-satellite Space research (space-to-Earth) ~~S5.560~~ADD S5.149A	
77.5-78	~~RADIOLOCATION~~ AMATEUR AMATEUR-SATELLITE ~~Amateur~~ ~~Amateur-satellite~~ Radio astronomy Space research (space-to-Earth) ~~S5.560~~ADD S5.149A	
78-81	RADIO ASTRONOMY RADIOLOCATION Amateur Amateur-satellite Space research (space-to-Earth) S5.560 ADD S5.149A	

Reasons: The uplinks and downlinks of the fixed-satellite and mobile-satellite services, which had an allocation in the bands 71-74 GHz and 81-84 GHz are interchanged to avoid downlinks in band 81-84 GHz, as downlinks in the band 81-84 GHz cause interference to the radio astronomy service, which needs an allocation in the band 81-84 GHz; the paired uplinks for the FSS and MSS are in band 81-84 GHz.

In the band 74-76 GHz (originally 74-75.5 GHz) the link direction of the fixed-satellite service has been changed from Earth-to-space into space-to-Earth.

The broadcasting-satellite service has been moved from its original allocation 84-86 GHz to the band 74-76 GHz, as it is thought that a co-allocation of the BSS with the FSS allows a more efficient use of the spectrum than a co-allocation with the terrestrial broadcasting service, still allocated in the band 84-86 GHz. By doing so, one also achieves the result that interference is avoided to the radio astronomy service, which needs an allocation in the band 84-86 GHz.

In the band 76-77.5 GHz an additional allocation was given to the radio astronomy service. Throughout this proposal footnote S5.149 has been suppressed with the objective to replace it by a new footnote, either S5.149A, S5.149B, S5.149C or S5.149D. The objective of this proposal is to simplify this fairly complex footnote, and to improve its clarity. Detailed reasons are given in proposals EUR/13/163 to 166.

The amateur and amateur-satellite service are reallocated from the band 75.5-76 GHz to the band 77.5-78 GHz. In the sub-band 75.5-76 GHz, the footnote S5.EEE (EUR/13/182) is added to foresee a transition period up to the year 2005.

The allocation for the radiolocation service, originally in the band 76-81 GHz, is now only in the bands 76-77.5 GHz and 78-81 GHz. Additional allocations for the radiolocation service are given in the band 95-100 GHz. It should be noted that the band 76-77 GHz is used for vehicle anti-collision devices.

Primary allocations to the radio astronomy service have been added in the band 78-81 GHz. Both for the bands 76-77.5 GHz and 78-81 GHz, sharing with the radiolocation service is possible, based on geographical separation. With these allocations better opportunities are created for the radio astronomy service for observations in the so-called three mm window (76-102 GHz), which is of extreme importance for the RA service.

A secondary allocation to the radio astronomy service is added in the band 77.5-78 GHz (i.e. the newly proposed amateur band).

MOD EUR/13/155

66-86 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
81-84	FIXED FIXED-SATELLITE (~~space-to-Earth~~Earth-to-space) MOBILE MOBILE-SATELLITE (~~space-to-Earth~~Earth-to-space) RADIO ASTRONOMY Space research (space-to-Earth) ADD S5.149A ADD S5.DDD	

84-86	FIXED FIXED-SATELLITE (Earth-to-space) MOBILE BROADCASTING ~~BROADCASTING-SATELLITE~~ RADIO ASTRONOMY ~~S5.561~~ADD S5.149A

86-119.98 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
86-92	EARTH EXPLORATION-SATELLITE (passive) RADIO ASTRONOMY SPACE RESEARCH (passive) MOD S5.340	
92-94	FIXED ~~FIXED-SATELLITE (Earth-to-space)~~ MOBILE RADIO ASTRONOMY RADIOLOCATION ~~S5.149 S5.556~~ADD S5.149A ADD S5.FFF	

Reasons: The uplinks and downlinks of the fixed-satellite and mobile-satellite services, which had an allocation in the bands 71-74 GHz and 81-84 GHz are interchanged to avoid downlinks in band 81-84 GHz, as downlinks in the band 81-84 GHz cause interference to the radio astronomy service, which needs an allocation in the band 81-84 GHz; the paired downlinks for the FSS and MSS are in band 71-74 GHz.

S5.DDD (EUR/13/181) appears for the sub-band 81-81.5 GHz to maintain the total of 5 GHz secondary allocation for the amateur services.

The broadcasting-satellite service has been reallocated from the band 84-86 GHz to the band 74-76 GHz, to avoid interference to the radio astronomy service, which needs an allocation in the band 84-86 GHz. Furthermore, it is assumed that convergence of services will lead to a more efficient use of the spectrum when the BSS and FSS are co-allocated. Sharing between comparable satellite services will be easier than sharing between satellite services and terrestrial services.

Footnote S5.561 has been moved, with its related services, to the band 74-76 GHz.

The fixed-satellite service (Earth-to-space) which was removed from the band 74-75.5 GHz, has been given a new allocation in the bands 84-86 GHz.

For the band 86-92 GHz, no change is proposed: this band is of crucial importance for the EESS and SR; it is the window for the EESS (p) and SR (p) band around 118.75 GHz; it is also used to detect precipitation. The fact that no active services are acceptable in this band is reflected via footnote MOD S5.340.

Footnote S5.556 is deleted since it is not necessary any more: the radio astronomy service has now a primary allocation in the band 92-94 GHz.

The FSS has been removed from the band 92-94 GHz, as it cannot share with the RA; compensation has been given in the bands 81-84 GHz and 84-86 GHz.

MOD EUR/13/156

86-119.98 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
94-94.1	EARTH EXPLORATION-SATELLITE (active) RADIOLOCATION SPACE RESEARCH (active) Radio astronomy S5.562 ADD S5.FFF	
94.1-95	FIXED ~~FIXED-SATELLITE (Earth-to-space)~~ MOBILE RADIO ASTRONOMY RADIOLOCATION ADD S5.149A ADD S5.FFF	
95-100	FIXED MOBILE ~~S5.553~~ ~~MOBILE-SATELLITE~~ RADIO ASTRONOMY RADIOLOCATION RADIONAVIGATION RADIONAVIGATION-SATELLITE ~~Radiolocation~~ ~~S5.149~~ ADD S5.149A MOD S5.554 ~~S5.555~~	
100-102	EARTH EXPLORATION-SATELLITE (passive) ~~FIXED~~ ~~MOBILE~~ RADIO ASTRONOMY SPACE RESEARCH (passive) MOD S5.340 S5.341	
102-105	FIXED ~~FIXED-SATELLITE (space-to-Earth)~~ MOBILE RADIO ASTRONOMY ADD S5.149A S5.341	

Reasons: As already indicated in the current Article S5 of the Radio Regulations via footnotes S5.149, S5.555 and S5.556 these bands are of importance for the radio astronomy service. The band 95-100 GHz had already a primary allocation in the European common Table of Frequency Allocations. With these allocations better opportunities are created for the radio astronomy service for observations in the so-called three mm window (76-102 GHz), which is of extreme importance for the RA service.

The RA has been given a secondary allocation in the band 94-94.1 GHz since it has already allocations in the adjacent bands above and below; due to the wideband characteristics of the RA receivers, the use of this band during the observations cannot be avoided. Available band stop filter technology in radio astronomy receivers, in combination with geographical coordination will avoid damage to RA receivers. Footnote S5.FFF (EUR/13/183) indicates the need for coordination of the activities of EESS (a) and RAS users.

Footnote S5.149, needs modification as a consequence of this allocation proposal; see relevant proposal elsewhere (see EUR/13/163 to 167). EUR/13/173 proposes the required modification for S5.556, which in this frequency band can be deleted as a consequential.

The fixed-satellite service has been removed from the band 94.1-95 GHz, and the MSS was removed from the band 95-100 GHz, as these services cannot share with the radio astronomy service; compensation for these lost allocations has been given in the bands 81-84 GHz and 84-86 GHz.

Footnote S5.553 can be deleted from the band 95-100 GHz; apart from the radionavigation-satellite service there are no space radiocommunications any more in this band.

The band 100-102 GHz (NO line at 100.49 GHz) is used by the IKAR satellite for limb sounding; sharing between EESS (p) and SR (p) and fixed or mobile services is, for the time being, considered not to be feasible. Potential sharing in the future with the fixed and mobile services needs sharing constraints for the FS and MS which have to be laid down in an ITU-R recommendation.

For footnote MOD S5.554, see EUR/13/171 (the proposed modification is not relevant for the band 95-100 GHz).

119.98-158 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
119.98-120.02	EARTH EXPLORATION-SATELLITE (passive) ~~FIXED~~ INTER-SATELLITE ADD S5.JJJ ~~MOBILE S5.558~~ SPACE RESEARCH (passive) ~~Amateur~~ S5.341	
120.02-~~126~~122.25	EARTH EXPLORATION-SATELLITE (passive) ~~FIXED~~ INTER-SATELLITE ADD S5.JJJ ~~MOBILE S5.558~~ SPACE RESEARCH (passive) S5.138	

Reasons: The EESS (p) does not need the bands 105-109.5 GHz and 111.8-114.25 GHz.

The SR (p) needs the band 105-109.5 GHz and 111.8-114.25 GHz for space-based radio astronomy; this is explained in S5.CCC (EUR/13/180).

With the deletion of the EESS (p) from the band 105-109.5 GHz, an additional allocation can be made to the fixed and mobile services; therefore S5.340 is no longer applicable.

For the band 109.5-111.8 GHz, no change is proposed, as compared to the current allocation; only footnote S5.340 needs modification to reflect the correct frequency bands; this band is and will be used by the EESS (p) for limb sounding (Ozone line at 110.8 GHz); sharing with active services in this band is considered not to be feasible; for potential future sharing scenario's the draft new Resolution XXX [EUR/13/7] is proposed (see EUR/13/188).

The band 105-116 GHz, in particular 109.5-111.8 GHz is of vital importance to the radio astronomy service for spectral line observations. Observations of the CO molecule and its isotopic variants are carried out. Moreover, it should be noted that observations of the stratospheric ozone line at 110.836 GHz are carried out by ground-based stations.

The band 114.25-122.25 GHz is of crucial importance for the EESS and SR as it is the oxygen absorption band. The centre of the oxygen absorption band is at 118.73-118.77 GHz. The associated window (reference) is in band 86-92 GHz. It has to be clean passive band; however the inter-satellite service can share with the EESS (p), SR (p) and RA when certain conditions are fulfilled (footnote S5.JJJ, see EUR/13/184). Therefore the fixed and mobile services have been removed from this band (reallocated to the bands 105-109.5 GHz and 111.8-114.25 GHz). Also the secondary allocation for the amateur services has been reallocated (to the bands 122.25-123 GHz and 136-141 GHz. Much radio astronomy work is done in this frequency range, especially again CO spectral line measurements (the main CO line is at the frequency 115.27 GHz).

The Odin and other satellites use both the allocations to the EESS (p) and RA service to observe the O2 line within the range 118.25-119.25 GHz.

The deletions or modifications to S5.340 and S5.351 are consequential.

MOD EUR/13/158

130-134	EARTH EXPLORATION-SATELLITE (active) ADD S5.LLL FIXED INTER-SATELLITE MOBILE MOD S5.558 ~~RADIOLOCATION S5.559~~ RADIO ASTRONOMY ADD S5.149A	

Reasons: The bands 122.25-123 GHz and 123-130 GHz are not needed by EESS and SR. In the lower band an allocation has been given to the fixed and mobile services; in the upper band services which had to be removed from bands above 134 GHz have found an allocation (e.g. the radionavigation and radionavigation-satellite services. By splitting the band 122.25-130 GHz into two sub-bands, a guardband between these allocations and the allocation for the passive services in the adjacent lower band was created. The fixed, mobile and inter-satellite services were removed from the band 123-130 GHz to avoid sharing difficulties.

S5.558 has been modified to reflect the new frequency bands.

In the band 130-134 GHz the radiolocation service was removed in order to create a “good quality” band for the fixed and mobile service; radiolocation found a new allocation in the band 136-141 GHz.

In order to allow the use of a frequency band above 100 GHz for EESS (active) for altimetry, an allocation for this service has been added, with footnote S5.LLL (EUR/13/186), limiting this allocation to the range 130-130.5 GHz.

S5.340 is not applicable any more in the bands 105-109.5 GHz, and 111.8-114.25 GHz (see EUR/13/168).

S5.149 has been replaced by S5.149A according to the principles explained in EUR/13/163 to 167.

Footnote S5.554, relating specific use within the mobile-satellite and radionavigation-satellite services, originally in the band 134-142 GHz, has been moved to the new band for these services: 123-130 GHz (see EUR/13/171).

158-202 GHz

Allocation to services		
Region 1	**Region 2**	**Region 3**
158.5-164	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE MOBILE-SATELLITE (space-to-Earth)	

Reasons: The amateur and amateur-satellite services have been reallocated from the band 142-144 GHz to the band 134-136 GHz, in order to avoid interference to the radio astronomy service which has a high interest in the band 142-144 GHz.

The mobile service originally in this band was moved to the band 141-148.5 GHz; the mobile-satellite, radionavigation and radionavigation-satellite services have been moved to the band 123-130 GHz.

The radiolocation service, now appearing in the bands 136-141 GHz, 141-148.5 GHz and 151.5-155.5 GHz, had originally its allocation in the bands 130-134 GHz and 144-149 GHz. These changes allow an easy sharing situation in the bands 136-155.5 GHz, taking into account in particular the need for the removal of active services from the band 148.5-151.5 GHz, as well as the fact that sharing between the radiolocation service and the radio astronomy service is considered to be feasible.

The radio astronomy service had up to now only several narrow-bands allocated in the frequency range 120-190 GHz, the so-called two mm window; with this new allocation picture a large contiguous block of spectrum could be allocated to this service necessary for observations of spectral lines from a large variety of molecules and for continuum observations (i.e. for cosmic background research).

The band 148.5-151.5 GHz is of crucial importance for the EESS (p) and SR (p); it has now been made available to these services, replacing the earlier allocation in the band 150-151 GHz, which was too narrow. In practice the band 149-151 GHz was already used.

The band will be used as a window (reference) for the observations in the band around 183.31 GHz. Nowadays also the bands 155.5-157.5 GHz and 166-168 GHz are in use as such windows. In this proposal, it is foreseen that in the future only two bands will be used for such a window; these will be the harmonized bands 148.5-151.5 GHz and 164-167 GHz. Two frequency bands will offer a better referencing than one wide frequency band. See further specific notes at band 155.5-157.5 GHz.

The fixed-satellite (space-to-Earth) allocation originally appearing in the band 151-156 GHz, was removed from the bands 151.5-155.5 GHz and 155.5-158.5 GHz, as downlinks are incompatible with primary radio astronomy bands, and the EESS (p) and SR (p); compensation is found in the bands 123-130 GHz and 167-174 GHz.

The band 155.5-158.5 GHz is now in use by the EESS and SR as a window for the observations in the band around 183.31 GHz. In the future (after 01/01/2018) the harmonized bands 148.5-151.5 GHz and 164-167 GHz are foreseen.

The date chosen (via footnote S5.AAA, see EUR/13/178) allows time for development and exploitation of a system presently under development. After 01/01/2018 the band can be used by the fixed and mobile service; such is foreseen via footnote S5.BBB, see EUR/13/179. The allocation to space research continues, but limited to space-based radio astronomy (footnote S5.CCC, EUR/13/180).

In the band 158.5-164 GHz, the mobile-satellite service was added in order to compensate for losses in allocation elsewhere:

– for footnote S5.149A, see EUR/13/163 to 167

– for footnote MOD S5.340, see EUR/13/168

– for the deletion of footnote S5.385, see EUR/13/169.

191.8-200	FIXED INTER-SATELLITE MOBILE ~~S5.553~~ MOBILE-SATELLITE RADIONAVIGATION RADIONAVIGATION-SATELLITE S5.341 MOD S5.554

Reasons: The band 164-167 GHz, together with the band 148.5-151.5 GHz, will in future be the harmonized “window” (reference) for the EESS observations of the 183.31 GHz water vapour line. This band is of crucial importance for the EESS and SR.

From the band 167-174.5 GHz, the 1 GHz used for the “passive services”, can be deleted; an allocation for the fixed-satellite service has been added to compensate for losses of allocation space elsewhere (e.g. 158-164 GHz).

The inter-satellite service had originally its allocation in the band 170-174.5 GHz.

The allocations in the band 174.5-174.8 GHz are identical with those proposed for the band 167-174 GHz, except for the fixed-satellite; this has been done to create a better protection scenario for the upper adjacent pure passive band.

The band 174.8-191.8 GHz is of crucial importance for passive sensing of the water vapour absorption line whose peak is at 183.31 GHz. The central part of the band, 182-185 GHz, is kept as a purely passive band. Radio astronomers wish to use this band for calibration of their receivers, and also to do observations from aircraft.

The ISS service needs to be limited to links between GSO satellites and to a pfd limit as specified in sharing studies, therefore footnote S5.KKK (see EUR/13/185). This allocation protects also the NO line at 175.86 GHz, the ozone line at 184.75 GHz, and the nitric-acid (HNO3) line at 191.595 GHz.

The fixed service has been added to the existing allocations in the band 191.8-200 GHz, taking account of the principle of convergence of the fixed and mobile services; also the inter-satellite service has been added to grant it more quantity and quality of allocation.

Footnotes S5.149, S5.340 and S5.558 are modified to reflect the new frequency bands (see EUR/13/163 to 167, EUR/13/168 and EUR/13/174 respectively).

Footnote S5.385, dealing with a secondary allocation for radio astronomy needs modification: partly because a primary allocation was made, partly because no allocation was made (see EUR/13/169).

Footnote S5.554 has been modified to reflect the correct frequency bands (see EUR/13/171).

231.5-232	FIXED ~~FIXED-SATELLITE (space-to-Earth)~~ MOBILE Radiolocation
~~231~~232-235	FIXED FIXED-SATELLITE (space-to-Earth) MOBILE Radiolocation

Reasons: The band 200-209 GHz is needed by EESS (p) using the technique of Limb Sounding for Atmospheric Chemistry; also ground-based atmospheric remote sensing will take place. The physical phenomena are the water vapour line at 203.4 GHz, the nitrous-oxide lines at 200.08 and 200.98 GHz, and the Ozone line at 208.5 GHz. For the radio astronomy, this band is used for measurements of spectral line emissions. Therefore the band has to be pure passive.

The frequency band 209-217 GHz is allocated to the fixed and mobile services (convergence), the fixed-satellite service (uplinks) and radio astronomy, a combination that can share on a geographical basis.

The band 217-226 GHz has the same allocations as its lower adjacent band; it is also foreseen that this band is used by space-based radio astronomy; therefore the allocation for SR (p) with the footnote S5.CCC (EUR/13/180).

The EESS (p) and SR (p) need in this frequency range only 5.5 GHz instead of the earlier allocation of 14 GHz (217-231 GHz). The band 226-231.5 GHz is required for limb sounding of various atmospheric constituents and to provide for a 4 GHz window for reference.

With regard to the radio astronomy service: the frequency band 217-231.5 GHz is of vital importance for astronomers; spectral line observations of a large variety of molecules, including red-shifted emission from the CO molecule and its isotropic variants are carried out; observation of CO spectral lines are carried out in conjunction with observations in the band 105-116 GHz.

265-275	FIXED FIXED-SATELLITE (Earth-to-space) MOBILE RADIO ASTRONOMY ~~S5.149~~ADD S5.149A
275-~~400~~1 000	(Not allocated) MOD S5.565

Reasons: The frequency band 235-238 GHz is used by the EESS (p) for Limb Sounding (ozone lines at 235.71 and 237.15 GHz); there is no consensus whether sharing between the passive services and the fixed/mobile services is feasible; to avoid unnecessary problems, the allocations for the fixed and mobile services have been deleted; proposal EUR/13/188 contains a draft new Resolution XXX [EUR/13/7], which calls for ITU-R studies.

Sharing between the EESS/SR (p) and the FSS (downlink) is considered feasible. The FSS has in this frequency range now an allocation of total 8.5 GHz.

Footnote S5.NNN (see EUR/13/187) was added to foresee in a frequency band of 100 MHz which can be used by the EESS (a) and SR (a) for spaceborne cloud radars only, such to complement the measurements in the band 94-94.1 GHz.

In the band 238-240 GHz, additional allocations have been made for the radiolocation, radionavigation, and radionavigation-satellite services to compensate for “losses” in the frequency ranges 150-160 GHz and 170-200 GHz respectively. One could also say: in this range the secondary allocation for radiolocation was made a primary.

The band 240-241 GHz is allocated to terrestrial services only, to avoid interference problems with the adjacent upper band, which is important for radio astronomy.

With regard to the bands 241-248 GHz, and 250-252 GHz, the major change is the addition of the radio astronomy service; this service can share with the radiolocation, based on geographical separation.

With the development of “millimetre-technology” within the radio astronomy community, observations in the spectrum above 241 GHz have shown to be very important for this science: numerous spectral lines indicate a huge variety of physical/chemical processes.

The band 250-252 GHz is used by the EESS (p) and SR (p) for Limb Sounding (nitrous-oxide line at 251.21 GHz); sharing with terrestrial services is considered not to be feasible; (see the draft new Resolution XXX [EUR/13/7] in EUR/13/188).

In the band 252-265 GHz, the fixed service was added (apart from the addition of the radio astronomy service), taking into consideration the phenomena of convergence.

For the deletion of footnote S5.149 and addition of footnote S5.149A, see EUR/13/163 to 167.

For the modification of footnote S5.340, see EUR/13/168.

Footnote S5.385 has been deleted, since it specified an additional allocation for radio astronomy in certain bands; however to reflect the new situation, the footnote itself needs modification; see EUR/13/169.

For the modification of footnote S5.554, see EUR/13/171.

Footnote S5.564, specifying some countries that had a primary allocation for the radio astronomy service in the band 261-265 GHz is deleted, as this is now covered by the newly proposed Table of Frequency Allocations (see EUR/13/176).

Footnote S5.565 has been modified to indicate the interests of the radio astronomy, the Earth exploration-satellite and space research services in various specific frequency bands in the range 275-1 000 GHz (see EUR/13/177). To allow such an indication, the Table of Frequency Allocations has been extended to cover also the range 400-1 000 GHz.

608-614 MHz in Regions 1 and 3,	31.2-31.3 GHz,

are allocated, administrations are urged to take all practicable steps to protect the continuum observations done in the radio astronomy service from harmful interference. Emissions from spaceborne or airborne stations can be particularly serious sources of interference to the radio astronomy service (see Nos. **S4.5** and **S4.6** and Article **S29**).

Reasons: The frequency bands mentioned in the current footnote S5.149 refer either to the boundaries of the cells specified in the Table of Frequency Allocations, or to sub-bands within the bands specified in these cells.

The present structure of S5.149 implies that any time a re-allocation is made touching any of the boundaries specified in the frequency bands mentioned in S5.149, the footnote itself needs modification. This has to be considered as an unnecessary complexity.

Noting that the prime objective of the footnote is to foresee protection of the radio astronomy, the solution to the problem can be found in making the footnote, wherever possible, independent from the frequency band to which it appears.

Further elaboration of this idea leads to the conclusion that S5.149 should be split into four new footnotes; a first division into two to allow a differentiation in protection of spectral line and continuum observations, and a second division of these two, which brings us to four, to enable the specification of (a) sub-band(s) within the band mentioned in a specific cell. In case a band is mentioned both for continuum and for spectral line observations, such a band will only be mentioned under continuum, as the protection requirements for continuum are more severe than those for spectral line observations. This leads to the four footnotes, which replace S5.149:

S5.149A for spectral line observations, applicable to the full frequency band mentioned in the cell in which it appears;

S5.149B for continuum observations, applicable to the full frequency band mentioned in the cell in which it appears;

S5.149C for spectral line observations, applicable to only a part of the frequency band mentioned in the cell in which it appears;

S5.149D for continuum observations, applicable to only a part of the frequency band mentioned in the cell in which it appears.

250-252 GHz.	

Reasons: To reflect the new frequency bands.

MOD EUR/13/169

S5.385 *Additional allocation:* the bands 1 718.8-1 722.2 MHz~~, 150-151 GHz, 174.42-175.02 GHz, 177-177.4 GHz, 178.2-178.6 GHz, 181-181.46 GHz, 186.2-186.6 GHz and 257.5-258 GHz are~~ is also allocated to the radio astronomy service on a secondary basis for spectral line observations.

Reasons: To reflect the new allocations.

MOD EUR/13/170

S5.553 In the bands 43.5-47 GHz~~,~~ and 66-71 GHz~~, 95-100 GHz, 134-142 GHz, 190-200 GHz and 252-265 GHz~~, stations in the land mobile service may be operated subject to not causing harmful interference to the space radiocommunication services to which these bands are allocated (see No. **S5.43**).

Reasons: This footnote is not applicable any more to most of the bands above 71 GHz, because in most cases the sharing scenario has been changed in the newly proposed table; in some cases, the results of sharing studies have to be awaited, before “priority arrangements” are to be defined.

MOD EUR/13/171

S5.554 In the bands 43.5-47 GHz, 66-71 GHz, 95-100 GHz, ~~134-142~~123-130 GHz, ~~190~~191.8-200 GHz and 252-265 GHz, satellite links connecting land stations at specified fixed points are also authorized when used in conjunction with the mobile-satellite service or the radionavigation-satellite service.

Reasons: To reflect the new allocations.

MOD EUR/13/172

S5.555 *Additional allocation:* the bands 48.94-49.04 GHz~~, 97.88-98.08 GHz, 140.69-140.98 GHz, 144.68-144.98 GHz, 145.45-145.75 GHz, 146.82-147.12 GHz, 250-251 GHz and 262.24-262.76 GHz are~~ is also allocated to the radio astronomy service on a primary basis.

Reasons: To reflect to the new Table of Frequency Allocations correctly in this footnote; the radio astronomy has got a primary allocation in the table itself instead of via a footnote.

MOD EUR/12/173

S5.556 In the bands 51.4-54.25 GHz, 58.2-59 GHz~~,~~ and 64-65 GHz~~, 72.77-72.91 GHz and 93.07-93.27 GHz~~, radio astronomy observations may be carried out under national arrangements.

Reasons: In the newly proposed Table of Frequency Allocations, there is no need for this footnote to reflect frequency bands above 71 GHz.

MOD EUR/12/174

S5.558 In the bands 55.78-58.2 GHz, 59-64 GHz, 66-71 GHz, ~~116-134 GHz, 170-182 GHz and 185-190 GHz,~~122.25-123 GHz, 130-134 GHz, 167-174.5 GHz and 174.5-174.8 GHz, stations in the aeronautical mobile service may be operated subject to not causing harmful interference to the inter-satellite service (see No. **S5.43**).

Reasons: To reflect the new frequency bands.

MOD EUR/12/175

S5.561 In the band ~~84-86~~74-76 GHz, stations in the fixed~~,~~ and mobile~~ and broadcasting~~ services shall not cause harmful interference to stations of the fixed-satellite service or stations of the broadcasting-satellite ~~stations~~services operating in accordance with the decisions of the appropriate frequency assignment planning conference for the broadcasting-satellite service.

Reasons: To reflect the new frequency band and the new sharing-scenario in this band. A convergence between the BSS and FSS is assumed.

SUP EUR/12/176

S5.564

Reasons: Not needed any more, as allocation is foreseen in table.

MOD EUR/12/177

S5.565 The frequency band 275-~~400~~1 000 GHz may be used by administrations for experimentation with, and development of, various active and passive services. In this band a need has been identified for the following spectral line measurements for passive services:

– radio astronomy service: ~~278-280~~275-323 GHz~~ and 343-348 GHz,~~ 327-371 GHz, 388-424 GHz, 426-442 GHz, 453-510 GHz, 623-711 GHz, 795-909 GHz and 926-945 GHz;

– Earth exploration-satellite service (passive) and space research service (passive): 275-277 GHz, ~~300-302 GHz, 324-326 GHz, 345-347 GHz,~~ 294-306 GHz, 316-334 GHz, 342-349 GHz, 363-365 GHz~~ and 379-381 GHz~~, 371-389 GHz, 416-434 GHz, 442-444 GHz, 496-506 GHz, 546-568 GHz, 624-629 GHz, 634-654 GHz, 659-661 GHz, 684-692 GHz, 730-732 GHz, 851-853 GHz and 951-956 GHz.

Future research in this largely unexplored spectral region may yield additional spectral lines and continuum bands of interest to the passive services. Administrations are urged to take all practicable steps to protect these passive services from harmful interference until the next competent world radiocommunication conference.

Reasons: To indicate more precisely the interests of the radio astronomy, the Earth exploration-satellite and space research services in specific frequency bands in the range 275-1 000 GHz. In fact some of these frequency bands are already used for the radio astronomy and the EESS/SR (p). Satellites operating in frequency bands going up to 2.5 THz are under development.

ADD EUR/13/178

S5.AAA In the band 155.5-158.5 GHz, the allocation to the Earth exploration-satellite service (passive) and space research service (passive) shall terminate on 1 January 2018.

Reasons: The band 155.5-158.5 GHz is now in use by the EESS and SR as a window for the observations in the band around 183.31 GHz. In the future the harmonized bands 148.5-151.5 GHz and 164-167 GHz are foreseen. This provision allows time for development and exploitation of a system presently under development.

ADD EUR/13/179

S5.BBB The date of entry for the allocations to the fixed and mobile services in the band 155.5-158.5 GHz shall be 1 January 2018.

Reasons: The band 155.5-158.5 GHz is now in use by the EESS and SR as a window for the observations in the band around 183.31 GHz. In the future the harmonized bands 148.5-151.5 GHz and 164-167 GHz are foreseen. This provision allows time for development and exploitation of a system presently under development.

ADD EUR/13/180

S5.CCC The use of this allocation is limited to space-based radio astronomy only.

Reasons: To reflect the needs for the radio astronomy, whilst avoiding potential problems of interference.

ADD EUR/13/181

S5.DDD The band 81-81.5 GHz is also allocated to the amateur and amateur-satellite services on a secondary basis.

Reasons: The amateur and amateur-satellite services had in the current Table of Frequency Allocations a secondary allocation of 5 GHz in the band 76-81 GHz; in this proposal this allocation has been shifted to the bands 76-77.5 GHz and 78-81.5 GHz.

ADD EUR/13/182

S5.EEE The band 75.5-76 GHz is also allocated to the amateur and amateur-satellite services on a primary basis until the year 2005.

Reasons: To allow a time period for the amateur and amateur-satellite services to move to the newly allocated bands.

ADD EUR/13/183

S5.FFF Due to the common scientific nature of the two services, the operations of the space station in the Earth exploration-satellite service (active) in the frequency band 94-94.1 GHz shall be coordinated with the radio astronomy stations operating in the frequency bands 92-94 GHz and 94.1-95 GHz to avoid damage to the radio astronomy receivers, to minimize the time duration of harmful interference to radio astronomy stations and to maximize the observation time of the space station.

Reasons: Coordination between the cloud radar operations and the affected radio astronomy stations would prevent physical damage to radio astronomy systems and would allow time sharing between these different scientific applications.

Coordination methods could be:

– specification of pfd limits to protect the radio astronomy service;

– adequate filtering;

– switching off the space station transmissions over the affected radio astronomy stations;

– switching off the radio telescopes of the affected radio astronomy stations during passes of the cloud radar satellite.

Reason to indicate coordination purpose:

To explain the coordination goal and prevent future confusion. At this moment, those who participated in the development of this footnote know the background and mutual agreements but it cannot be excluded that in the future other people interpret the coordination differently, e.g. full protection of radio astronomy at all times whilst putting inappropriate burden on the space station. It is felt that with this language this could be prevented.

ADD EUR/13/184

S5.JJJ The use of the band 116-122.25 GHz by the inter-satellite service is limited to satellites in the geostationary-satellite orbit. The single-entry power flux-density, at all altitudes from 0 km to 1 000 km above the Earth’s surface and in the vicinity of all geostationary orbital positions occupied by passive sensors, produced by a station in the inter-satellite service, for all conditions and for all methods of modulation, shall not exceed –148 dBW/m^2/MHz for all angles of arrival.

Reasons: To allow the sharing between the ISS and the EESS (p) and SR (p).

ADD EUR/13/185

S5.KKK The use of the band 174.8-182 GHz by the inter-satellite service is limited to satellites in the geostationary-satellite orbit. The single-entry power flux-density, at all altitudes from 0 km to 1 000 km above the Earth’s surface and in the vicinity of all geostationary orbital positions occupied by passive sensors, produced by a station in the inter-satellite service, for all conditions and for all methods of modulation, shall not exceed –144 dBW/m^2/MHz for all angles of arrival.

Reasons: To allow the sharing between the ISS and the EESS (p) and SR (p).

ADD EUR/13/186

S5.LLL The allocation to the Earth exploration-satellite service (active) and the space research service (active) is limited to the band 130-130.5 GHz.

Reasons: To allow the EESS (a) and SR (a) the use of some frequencies above 71 GHz for high resolution altimetry.

ADD EUR/13/187

S5.NNN The frequency band 237.9-238 GHz is also allocated to the Earth exploration-satellite service (active) and the space research service (active) for spaceborne cloud radars only.

Reasons: To allow the use of this small part of the spectrum to carry out these measurements which are complementary to the measurements done in the band 94-94.1 GHz, such to improve the accuracy.

ADD EUR/13/188

RESOLUTION XXX [EUR/13/7] (WRC-2000)

Consideration by a future competent world radiocommunication conference of issues dealing with sharing and adjacent band compatibility above 71 GHz

The World Radiocommunication Conference (Istanbul, 2000),

considering

a) that WRC-2000 made changes to the Table of Frequency Allocations above 71 GHz, following consideration of science service issues;

b) that several bands above 71 GHz are already used by EESS (passive) and SR (passive) because they are unique bands to measure specific atmospheric parameters;

c) that several bands above 71 GHz are already used by the radio astronomy service;

d) that in order to ensure the protection of passive services above 71 GHz, WRC-2000 avoided co-allocations of active and passive services to prevent potential sharing problems;

e) that there are several co-primary active services in some bands above 71 GHz in the Table of Frequency Allocations as revised by WRC-2000;

f) that in some cases satellite downlink allocations have been made within bands adjacent to those where radio astronomy is allocated;

g) that sharing between multiple co-primary active services may hinder the development of each active service in bands above 71 GHz,

noting

a) that preliminary sharing studies between active and passive services performed by ITU-R have not yet reached final conclusions due to the fact that the technical characteristics of the active services above 71 GHz are not yet known;

b) that sharing studies between active services have not yet been performed;

c) that interference criteria for passive sensors have been developed and are given in Recommendation ITU-R SA.1029;

d) that interference criteria for radio astronomy have been developed and are given in Recommendation ITU-R RA.769-1,

resolves

1 that sharing criteria for active services and their spectrum requirements be developed in bands above 71 GHz;

2 that further studies be conducted:

2.1 to determine if and under what condition sharing is possible between terrestrial active services and passive services (EESS and SR) in the bands 100-102 GHz, 114.25-122.25 GHz, 148.5-151.5 GHz, 174.8-191.8 GHz, 226-231.5 GHz and 235-238 GHz;

2.2 to determine if and under what condition sharing is possible between active services in bands above 71 GHz;

2.3 on adjacent band interference from space services (downlink) into radio astronomy in bands above 71 GHz;

3 that the necessary studies be completed as soon as the technical characteristics of the active services in these bands are known;

4 that a future conference should review, if necessary, the allocations above 71 GHz in the light of the studies performed under *resolves* 1, 2 and 3,

invites ITU-R

to develop recommendations specifying sharing criteria for those bands where sharing is feasible,

instructs the Secretary-General

to bring this Resolution to the attention of the international and regional organizations concerned.

Proposals submitted by the following administrations

Germany, Austria, Belgium, Bulgaria, Croatia, Denmark, Spain, Estonia, Finland, France, Hungary, Ireland, Iceland, Italy, Liechtenstein, Lithuania, Luxembourg, Norway, Netherlands, Poland, Portugal, Slovakia, Czech Rep., Romania, United Kingdom, Russia, Slovenia, Sweden, Switzerland, Turkey, Ukraine

PART 4B

Agenda item 1.17 - Worldwide allocation for the Earth exploration-satellite (passive) and space research services in the band 18.6-18.8 GHz

Introduction

The European common proposals for agenda item 1.17 seek to establish within the Radio Regulations the future sharing environment within which the FS, FSS and EESS (passive) must work. If agreement can be reached on the adoption of the technical constraints on the active services as proposed below, an upgrade of the EESS (passive) to worldwide primary status can be supported. These proposals are in line with technical options included in the CPM Report and represent the maximum constraint on the active services in this band which can be accepted by Europe.

In Europe the 18 GHz band is used extensively for fixed services in many countries and is likely to be used by the fixed-satellite service in the near future. The fixed service uses this band to provide mobile network infrastructure and medium hop links for public telecommunications networks. These requirements are expected to continue with the liberalization of European telecommunications and the introduction of new services. The proposal below is intended to safeguard the future increasing use of the band for all the allocated services.
